#### **EXECUTIVE SUMMARY**

Investigation of soil contamination at the 903 Drum Storage Area (903 Pad), 903 Lip Area (Lip Area), and Americium Zone was performed to provide characterization data for subsequent evaluation of remedial alternatives for site cleanup. Historically, drums which were stored at the 903 Pad between 1958 and 1967 leaked hydraulic fluids and lathe coolant containing plutonium and depleted uranium. This release contaminated surface and subsurface soil with radionuclides and volatile organic compounds (VOCs). The VOCs have migrated into the shallow groundwater system beneath the 903 Pad.

The primary purpose of this investigation was to estimate the volume of contaminated soil above the Rocky Flats Cleanup Agreement (RFCA) Tier I Radionuclide Soil Action Levels (RSALs) and Subsurface Soil Action Levels (SSALs). Another objective of the investigation was to characterize surface soil to 10 pCi/g americium-241 (<sup>241</sup>Am) using gamma spectroscopy field instrumentation. This characterization would allow for identification of surface soils exceeding Tier II RSALs. Remedial alternatives will be evaluated in the Interim Measure/Interim Remedial Action (IM/IRA) Decision Document based on these volume estimates.

Delineation of radiologically-contaminated soil in the Americium Zone was performed *insitu* using gamma-ray spectroscopy methods, which employ a high purity germanium detector (HPGe). The HPGe instrument was used to obtain 1110 contiguous gamma ray measurements with a circular field of view of 10 meters in diameter within the investigation area. Given this coverage, nearly the entire Americium Zone within the investigation area was surveyed for radionuclides.

The HPGe measurement results were correlated with alpha spectroscopy measurements of radionuclides in eight co-located surface soil samples. The resulting best-fit regression model was used to standardize each HPGe <sup>241</sup>Am measurement to a laboratory-derived <sup>241</sup>Am and plutonium-239/240 (<sup>239/240</sup>Pu) alpha spectroscopy measurement. The correlation results for <sup>241</sup>Am and <sup>239/240</sup>Pu were input into the Tier I and II RSAL sum of ratios equations to determine HPGe measurements locations exceeding the respective action levels.

Based on the standardized HPGe results, surface soil at approximately 37% of the HPGe measurement locations within the Americium Zone has radionuclides exceeding the Tier II RSALs. HPGe results that exceed Tier I RSAL are isolated at a cluster of three locations near the northwest corner of the Americium Zone and at one location in the south central portion of the Lip Area. The Tier I and Tier II RSAL exceedances are a result of elevated activities of <sup>239/240</sup>Pu and <sup>241</sup>Am. Within the Americium Zone, <sup>239/240</sup>Pu activities ranged from 6.32 pCi/g to 938.42 pCi/g and <sup>241</sup>Am activities ranged from 4.91 pCi/g to 149.22 pCi/g.

Contamination of surface and subsurface soils at the 903 Pad and Lip Area was delineated with data obtained from borings at evenly spaced grid nodes. Radiological samples from 79 boring locations were analyzed for <sup>241</sup>Am, <sup>239/240</sup>Pu, uranium-233/234 (<sup>233/234</sup>U), uranium-235 (<sup>235</sup>U), and uranium-238 (<sup>238</sup>U) using alpha spectroscopy. VOC samples were collected from 17 boring locations and were analyzed for VOC contaminants of concern which included carbon tetrachloride (CCL<sub>4</sub>), chloroform, cis-1,2-dichloroethene (1,2-DCE), methylene chloride, tetrachloroethene (PCE), and trichloroethene (TCE).

	Page:	ES-2 of ES-2

Based on the data obtained from borings in the 903 Pad and Lip Area, most of the surface soil (0 to 6 inches) is contaminated above Tier I and Tier II RSALs. <sup>239/240</sup>Pu and <sup>241</sup>Am activities within the 903 Pad and Lip Area ranged from 0.82 pCi/g to 152,260 pCi/g and 0.15 pCi/g to 31,670 pCi/g, respectively. Radiological contamination was also detected in the subsurface soil at depths of 6 to 12 inches and 12 to 18 inches within the 903 Pad and Lip Area; however, <sup>239/240</sup>Pu and <sup>241</sup>Am activities decreased by orders of magnitude at progressively deeper soil horizons.

Artificial fill at the 903 Pad is contaminated above the RFCA Tier II RSALs at one location (Boring 91898). Soil at this boring has elevated levels of <sup>241</sup>Am (126 pCi/g) and <sup>239/240</sup>Pu (558 pCi/g). Asphalt samples from the 903 Pad were also collected for waste characterization profiling but were not compared to RFCA Tier I and Tier II RSALs.

Contaminated soil volumes are based on the areas and depths of Tier I and Tier II RSAL exceedances. The total volume of contaminated soil exceeding Tier I RSALs is 2,235 m<sup>3</sup> (2,924 yds<sup>3</sup>). The total volume of soil exceeding Tier II RSALs is estimated at 11,287 m<sup>3</sup> (14,763 yds<sup>3</sup>). Relative to Tier II RSAL exceedances, the amount of radiologically-contaminated soil at the 903 Pad is 1,889 m<sup>3</sup> (2,471 yds<sup>3</sup>); in the Lip Area is 4,027 m<sup>3</sup> (5,267 yds<sup>3</sup>); and in the Americium Zone is 5,371 m<sup>3</sup> (7,025 yds<sup>3</sup>).

No VOCs were detected in subsurface soil above the current SSALs within the 903 Pad and Lip Area. However, PCE, TCE and 1,2-DCE exceeded proposed Tier I and Tier II SSALs in several borings near well 08891. The total volumes of contaminated soil above proposed Tier I and Tier II SSALs are 558 yds<sup>3</sup> and 3,566 yds<sup>3</sup>, respectively. In addition, 138 yds<sup>3</sup> of contaminated soil containing elevated levels of both radionuclides and VOCs are also present.

#### 1.0 INTRODUCTION

This report summarizes data collected to determine the location, area, and volume of soil potentially requiring evaluation, management, or remedial action at Individual Hazardous Substance Site (IHSS) 112 - 903 Drum Storage Area (903 Pad), IHSS 155 - 903 Lip Area (Lip Area) and Americium Zone, located at the Rocky Flats Environmental Technology Site (RFETS). Figure 1-1 provides the locations of the IHSSs and the Americium Zone. Remedial alternatives will be evaluated in the Interim Measures/Interim Remedial Action (IM/IRA) Decision Document based on these volume estimates.

Previous investigations have been conducted in these areas to evaluate the extent of contamination, and the data collected have been reported in the Operable Unit (OU) No. 2 Phase II Resource Conservation and Recovery Act (RCRA) Facility Investigation/ Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) Remedial Investigation (RFI/RI) Report (DOE, 1995). However, data from these earlier investigations do not provide the resolution necessary to accurately quantify the volume of soils that may require evaluation, management, or remedial action. Furthermore, with respect to VOC contaminated soils, the historical data do not support the presence of a separate phase dense non-aqueous phase liquid (DNAPL) at the 903 Pad, a model convincingly supported by groundwater data collected at this IHSS. Accordingly, the data reported herein were collected to fill these data gaps.

#### 1.1 SITE BACKGROUND

Waste releases at the 903 Pad (IHSS 112) are considered the primary source of radiological contamination in the surficial soil in this part of the RFETS. Drums that contained hydraulic fluids and lathe coolant contaminated with plutonium and uranium were stored at this location from the Summer of 1958 to January 1967. Approximately three fourths of the drums contained liquids contaminated with plutonium while most of the remaining drums contained liquids contaminated with uranium. Of the drums containing plutonium, the liquid was primarily lathe coolant and carbon tetrachloride in varying proportions. Also stored in the drums were vacuum pump oils, trichloroethene (TCE), tetrachloroethene (PCE), silicone oils, and acetone still bottoms (DOE, 1995).

Site Characterization Report for the	Document Number:	RF/RMRS-99-427.UN
903 Drum Storage Area,	Revision:	0
903 Lip Area, and Americium Zone	Date:	September 28, 1999
	Page:	2 of 109

Leaking drums were noted in 1964 during routine handling operations. The contents of the leaking drums were transferred to new drums, and the area was fenced to restrict access. When cleanup operations began in 1967, a total of 5,237 drums were at the drum storage site. Approximately 420 drums leaked to some degree. Of these, an estimated 50 drums leaked their entire contents. The total amount of leaked material was estimated at around 5,000 gallons of contaminated liquid containing approximately 86 grams of plutonium (DOE, 1995).

From 1968 through 1970, some of the radiologically-contaminated material was removed from the 903 Pad and Lip Area, some of the surrounding Lip Area was regraded, and much of the area was covered by an imported base coarse material. An asphalt cap was placed over the most contaminated area resulting in the 903 Pad. However, during drum removal and cleanup activities, wind and rain (stormwater erosion) spread plutonium-contaminated soils to the east and southeast from the 903 Pad area resulting in IHSS 155 (903 Lip Area). Several limited excavations have removed some of the plutonium-contaminated soils from the Lip Area (DOE, 1995; Barker, 1982; and RMRS, 1997a). However, results from the OU2 Phase II RFI/RI sampling and analysis and this investigation confirm that radiologically-contaminated soils remain.

Surface soils to the east and southeast of the Lip Area also exhibit elevated plutonium-239/240 (<sup>239/240</sup>Pu) and americium-241 (<sup>241</sup>Am) activities. This contamination is primarily attributed to wind dispersion from the 903 Pad with potential contributions from historical fires, stack effluent, and stormwater related surface soil erosion. Areas exhibiting elevated <sup>239/240</sup>Pu and <sup>241</sup>Am activities east and southeast of the Lip Area are known as the Americium Zone.

#### 1.2 ROCKY FLATS CLEANUP AGREEMENT

The Rocky Flats Cleanup Agreement (RFCA) is a legally binding agreement between the Department of Energy (DOE), the Environmental Protection Agency (EPA) and the Colorado Department of Public Health and Environment (CDPHE) to accomplish the required cleanup of radioactive and other hazardous substance contamination at the RFETS. Action levels and cleanup levels for interim remedial actions have been established for surface water, ground water, and soils and are presented in Attachment 5 of RFCA; "Action Levels and Standards Framework

Site Characterization Report for the	Document Number:	RF/RMRS-99-427.UN
903 Drum Storage Area,	Revision:	0
903 Lip Area, and Americium Zone	Date:	September 28, 1999
	Page:	3 of 109

for Surface Water, Ground Water, and Soils (ALF)" (K-H, 1999a). Surface soil is defined in the ALF as shallow soil to a depth of 6 inches (in) (15 cm). Subsurface soil is defined in ALF as soil deeper than 6 in (15 cm). Radionuclide Soil Action Levels (RSALs) for an open space future use scenario are the same for surface soils and subsurface soils.

Revisions to the Subsurface Soil Action Levels (SSALs) have been proposed which has resulted in revised Tier I action levels and the inclusion of new Tier II action levels for organic compounds. For this site characterization, contaminant concentrations in surface and subsurface soils have been compared to both Tier I and II RSALs, current Tier I SSALs, and proposed Tier I and Tier II SSALs (Kaiser-Hill, 1999a) in order to assist in the development of the best management strategy for site cleanup. In addition, an independent review of the soil action levels is currently being conducted by the Rocky Flats Soil Action Level Oversight Panel. Based on this independent review and the results from soil erosion modeling being performed by the Actinide Migration Evaluation Panel additional revisions to the soil action levels may be proposed in the future.

The parameters of interest include the activity/concentrations of the following radionuclides/compounds:

- Plutonium-239 /240 (<sup>239/240</sup>Pu);
- Americium-241 (<sup>241</sup>Am);
- Uranium-234 (<sup>234</sup>U);
- Uranium-235 (<sup>235</sup>U);
- Uranium-238 (<sup>238</sup>U); and
- VOCs (subsurface soils only).

Metals, semivolatile organic compounds, pesticides, and polychlorinated biphynels were eliminated as potential contaminants of concern based on data evaluation from previous investigations (DOE, 1995).

Site Characterization Report for the	Document Number:	RF/RMRS-99-427.UN

903 Lip Area, and Americium Zone	Date:	September 28, 1999
	Page:	4 of 109

**Radionuclides** - Table 1-1 provides the Tier I and Tier II RSALs for an open space future use exposure scenario.

Table 1-1 RFCA Tier I and II Radionuclide Soil Action Levels - Surface and Subsurface Soils

RADIONUCLIDE	TIER I RSAL (pCi/g)	TIER II RSAL (pCi/g)
<sup>241</sup> Am	215	38
<sup>239/240</sup> Pu	1429	252
<sup>234</sup> U	1738	307
<sup>235</sup> U	135	24
<sup>238</sup> U	586	103

If a mixture of radionuclide contaminants a, b, c are present in the soil with activities  $a_a$ ,  $a_b$ , and  $a_c$ , and if the applicable RSALs, are  $A_a$ ,  $A_b$ , and  $A_c$  respectively, then the activity in the soil shall be considered as exceeding the RSALs if the sum of ratios (SOR) is greater than 1, i.e.,

Sum of Ratios (SORs) = 
$$\frac{a_a}{A_a} + \frac{a_b}{A_b} + \frac{a_c}{A_c} > 1$$
 (Equation 1-1)

Volatile Organic Compounds - Table 1-2 provides the current Tier I SSALs and the proposed Tier I and Tier II SSALs for VOC contaminants of concern in soils at the 903 Pad.

#### 1.3 EXISTING DATA

Numerous investigations to assess the extent of contamination at the 903 Pad, Lip Area, and Americium Zone have been conducted. These investigations are briefly described below.

#### 1.3.1 Surface Soils

High Purity Germanium (HPGe) Surveys - HPGe surveys conducted in 1990 (EG&G, 1991) and 1994 (DOE, 1995; RMRS, 1997b) provide useful information on the activity of <sup>241</sup>Am in surface soils over the Americium Zone study area. These data were collected on a 150-foot grid to accommodate the HPGe detector's field of view (FOV) of 150 feet in diameter (17,671 ft²) (Figure 1-2). Surveys were not conducted over the 903 Pad and Lip Area and soil samples were not collected to supplement the surveys. The results from these surveys were utilized to define the boundaries of this characterization's investigation area.

Surface Soil Radiological Data - Surface soil samples were collected in support of the OU2 Phase II RFI/RI (DOE, 1995). As detailed in the RFI/RI, samples were collected utilizing two sampling methods; the Colorado Department of Health (CDH) sampling method and the Rocky Flats (RF) sampling method. Surface soil sample results were compared with Tier I RSALs. The results of the comparison indicated that samples collected from five 2.5-acre plots exceed the Tier I RSALs. These plots include two 2.5-acre plots (Plots 28 and 34) sampled using the CDH sampling method and three 2.5-acre plots (Plots 29, 36, and 46) sampled using the RF method (Figure 1-3).

#### 1.3.2 Subsurface Soils

Subsurface Soil Radiological Data - Three data sources were evaluated to determine the depth of radiological contamination within the study area: 1) RFI/RI borehole data (DOE, 1995); 2) RFI/RI soil profile pits (DOE, 1995); and 3) samples collected in support of a 1980 soil decontamination project (Rutherford, 1981). Results from the RFI/RI borehole samples were compared to RSALs and revealed that no samples exceed the Tier I RSALs. However, samples collected from soil profile pit TR08 exceeded Tier I RSALs to a depth of 27 centimeters (cm) (10.6 in). Soil profile pits were sampled at 3 cm (1.2 in) intervals to a total depth of 1 meter (m)

	Page:	6 of 109

(3.28 feet). Samples collected at soil profile pit TR06, located adjacent to pit TR08, were not analyzed because activities exceeded the DOT shipping requirements. It is assumed that radiochemical results from pit TR06 would also exceed Tier I RSALs, if analyzed.

Soil samples collected beneath the 903 Pad in support of the 1980 soil decontamination project exceeded Tier I RSALs to a depth of 66 cm (26-in) (RMRS, 1997b). This depth exceeds the thickness of the asphalt pad and the depth of imported base coarse material and indicates radiological contamination of natural undisturbed soils at the 903 Pad. However, no RFI/RI soil borings detected radiological contamination in excess of Tier I RSALs. As a result, a discrepancy with the depth of radiological contamination between these investigations exists.

Subsurface Soil VOC Data - Three sources of data were evaluated to determine the nature and extent of contamination at the 903 Pad: 1) RFI/RI borehole data (DOE, 1995); 2) IM/IRA soil gas survey results (DOE, 1994); and 3) groundwater monitoring well data.

Borehole sample results from the RFI/RI were compared with current Tier I SSALs revealed that no samples exceeded the current Tier I SSALs for organic contaminants. The soil gas survey indicated that the highest VOC concentrations were located immediately south of the southeast corner of the 903 Pad. Tetrachloroethene was detected at 27,000 micrograms per liter (ug/L) at a depth of 5 feet. However, at adjacent soil gas locations and boreholes, tetrachloroethene is either not detected or detected at very low concentrations. Soil gas concentrations for the remaining portion of the 903 Pad ranged from 0-500 ug/L with the highest concentrations around and north of monitoring well 08891 (Figure 1-4).

#### 1.3.3 Groundwater

A VOC-contaminated groundwater plume extends from the 903 Pad area to the east. The highest concentrations are found in groundwater samples collected from wells 06691 and 08891, which are located on the asphalt portion of the 903 Pad. Concentrations of contaminants in groundwater decrease rapidly moving eastward from the 903 Pad area. The primary groundwater contaminant in well 06691 is carbon tetrachloride with concentrations ranging from 51 to 100,000 ug/L. Methylene chloride (150 to 29,000 ug/L) and chloroform (92 to 46,000 ug/L) are also observed.

Site Characterization Report for the	Document Number:	RF/RMRS-99-427.UN
903 Drum Storage Area,	Revision:	0
903 Lip Area, and Americium Zone	Date:	September 28, 1999
	Page:	7 of 109

Groundwater sample results for well 08891 indicate the primary contaminant as PCE at concentrations ranging from 470 to 27,000 ug/L, along with carbon tetrachloride (290 to 17,000 ug/L), cis-1,2,dichloroethene (94 to 2,900 ug/L) and TCE (210 to 4,600 ug/L). The next highest concentration of carbon tetrachloride in groundwater is found in samples collected from well 13191, which is located west of the well 06691 and off the western edge of the 903 Pad. At this location, observed carbon tetrachloride levels ranged from 122 to 4,800 ug/L.

Concentrations of VOCs in groundwater decrease rapidly eastward from the 903 Pad area (DOE, 1995). For example, during the June 1998 groundwater sampling, well 06991 had 210 ug/L PCE and well 1587 had 880 ug/L PCE which are two orders of magnitude less than the concentration observed in well 08891 with 27,000 ug/L PCE (Figure 1-4).

Because of the complex nature of DNAPL transport and fate, DNAPL may often be undetected by direct methods leading to incomplete site assessments and inadequate remedial designs (EPA, 1992). A guide for estimating the potential for a DNAPL source at a site includes assessing if concentrations of DNAPL-related chemicals in groundwater are greater than 1% of the pure (single) phase solubility of the compound (EPA, 1992).

Table 1-3 provides a comparison of the pure single phase aqueous solubility and concentrations of DNAPL-compounds detected in groundwater at the 903 Pad (wells 06691 and 08891) from a June 1998 sampling event of monitoring wells 06691 and 08891. The comparison indicates that PCE and carbon tetrachloride have been detected in groundwater samples at 13.5% and 10.7% of their aqueous solubilities, respectively. These results and the known historical releases at the 903 Pad indicate there is a potential for pure phase organic contaminants in subsurface soils beneath the 903 Pad.

#### 1.4 SURFICIAL GEOLOGY

The surficial geology in the study area consists of Quaternary alluvium, colluvium and slump deposits along with artificial fill, soil and debris deposits, and disturbed soil. The surficial deposits overlie bedrock which consists of weathered claystone and minor bedrock sandstones of the Cretaceous Arapahoe and Laramie Formations. Surficial deposits consist of sandy clay and clayey gravel. Soil developed over the alluvium is rocky and sandy in contrast to the clayey soils developed over the claystone bedrock.

For this investigation, the surface and subsurface soils were subdivided into six soil horizons: (1) the Native 1 soil horizon consists of natural soils from 0 to 6 inches (surface soils); (2) the Native 2 soil horizon designates subsurface soils from 6 inches to 1 foot: (3) the Native 3 soil horizon designates subsurface soil from 1 to 1.5 feet; (4) the Native 4 soil horizon designates subsurface soil from 1.5 to 2.0 feet; (5) the Native group consists of Quaternary alluvium from the bottom of the Native 4 soil horizon (2.0 feet) to the bedrock contact; and (6) the Bedrock group consists of consolidated geologic material from the undifferentiated Laramie/Arapahoe Formations.

Artificial fill is present directly beneath the 903 Pad and in the Lip Area as a result of previous remediation activities. In November 1968 "slightly-contaminated" soil was graded from outside the fence at the 903 Pad into the fenced area to be capped. In September of 1969 a base coarse

	Page:	9 of 109

(artificial fill) material overlay, soil sterilant, and asphalt primer were constructed for the 903 "containment barrier" (Pad). The asphalt pad was constructed in October of 1969 and was reportedly 3 in (7.6 cm) thick. The thickness of the base coarse materials beneath the 903 Pad was assumed to be approximately 8 inches (20 cm). In February 1970, operations were initiated to apply additional fill (base coarse) over the Lip Area due to soil contamination. The thickness of the fill material reportedly ranged from 0.8 in (2 cm) to 5.1 in (13 cm) (DOE, 1995; RMRS, 1997b).

#### 1.5 SITE CONCEPTUAL MODEL

The contaminants present in the surface and subsurface soil are primarily a result of drum storage in the 903 Pad area. Drums containing hydraulic fluids and lathe coolant contaminated with plutonium and uranium leaked onto the surface soil. The liquids from the drums may have moved downward towards the bedrock surface, possibly carrying a fraction of the radionuclides into the subsurface along preferential pathways such as rodent holes, desiccation cracks, and/or along decayed roots. High winds and heavy rains spread the surficial radiological contamination outward from the 903 Pad, depositing it on surface soils in the Lip Area and Americium Zone.

Previous HPGe surveys from the study area and surface soil sample data show that, in general, higher concentrations are present near the 903 Pad, and concentrations decrease with increasing distance from the 903 Pad. Immediately east and south of the 903 Pad and Lip Area, there are areas of higher concentrations which may be the result of wind and surface water dispersion of contaminants (DOE, 1995). Accounting for the surface soil and HPGe sampling already collected from the 903 Pad area to Indiana Street, and the direction of surface water flow from the 903 Pad towards the South Interceptor Ditch, it was concluded that hot spots are not likely to be present to the east, outside of the Investigation Area (Figure 1-4).

The source of subsurface VOC contamination is suspected to be present directly beneath the area where drums were previously stored (DOE, 1995; RMRS; 1997b). The liquid contained in the drums may have migrated downward towards the bedrock surface. An east-west paleochannel is cut into the bedrock, with the greatest depth to bedrock located toward the middle of the 903 Pad (DOE, 1995; RMRS, 1997b; RMRS, 1997c). Available subsurface and groundwater VOC data

Site Characterization Report for the	Document Number:	RF/RMRS-99-427.UN
903 Drum Storage Area,	Revision:	0
903 Lip Area, and Americium Zone	Date:	September 28, 1999
	Page:	10 of 109

(see Section 1.3) indicates that any potential source of DNAPL contamination is limited to the area under the present 903 Pad. The VOC contamination east of the 903 Pad is limited to the dissolved phase in groundwater as supported by groundwater data (see Section 1.3.3) (DOE, 1995; RMRS, 1998e).

#### 1.6 PROJECT INVESTIGATION AREA

Based on the foregoing evaluation of the existing data in the study area, an Investigation Area was defined for this site characterization that represents the area where additional data is required to refine the volume estimate of contaminated soils (Figure 1-4). The Investigation Area represents that portion of the study area which is known, or in which a potential exists, for surface and/or subsurface soils to exceed Tier I RSALs and current Tier I SSALs. These areas include:

- Surface soils exceeding 10 pCi/g <sup>241</sup>Am as identified in the 1990 and 1994 HPGe surveys;
- Areas where artificial fill (and asphalt) has been placed over natural soils including the 903
   Pad, Lip Area, and areas remedied in 1976, 1978, and 1984;
- Five 2.5-acre plots identified as exceeding Tier I soil action levels based on OU2 RFI/RI surface soil sampling results: and
- The 903 Pad and Lip Area where a subsurface VOC source is suspected as the source of a groundwater contaminant plume.

## 2.0 FIELD INVESTIGATION

#### 2.1 OVERVIEW

The lateral and vertical extent of radiological and VOC contamination was assessed within the proposed investigation area. The lateral extent of radiological contamination in the Americium Zone and a portion of the Lip Area were primarily assessed using a non-intrusive HPGe field method. The HPGe method results were "standardized" by correlation to radiochemical data collected by sampling surface soils from selected HPGe measurement locations, and analyzing these samples for radionuclides using alpha spectroscopy. The lateral and vertical extent of contamination at the 903 Pad and a majority of the Lip Area were assessed utilizing sample collection methods employing a Geoprobe®, and analyzing the samples for radionuclides and VOCs in a laboratory. The data were collected pursuant to the Sampling and Analysis Plan for the Site Characterization of the 903 Drum Storage Area (IHSS 112), 903 Lip Area (IHSS 155), and Americium Zone (SAP) (RMRS, 1998a).

#### 2.2 SURFACE SOIL INVESTIGATION

The activities of <sup>241</sup>Am, <sup>239/240</sup>Pu, <sup>233/234</sup>U, <sup>235</sup>U, and <sup>238</sup>U in surface soils within the Americium Zone and a portion of the Lip Area were measured *in situ* using an HPGe survey together with radiochemical analyses of surface soil samples.

## 2.2.1 HPGe Methodology

The HPGe instrument measures *in situ* activities of <sup>241</sup>Am, <sup>235</sup>U and <sup>238</sup>U. For this investigation, the HPGe measurement had a field of view (FOV) of 10 meters (m) in diameter with the detector placed 1-m over the ground surface. The Compendium of *In Situ* Radiological Methods and Applications at Rocky Flats Plant (EG&G, 1993) provides a detailed discussion on the physics of *in situ* measurement of radionuclides in the environment.

The HPGe survey focused on the Americium Zone (Figure 2-1) and includes all surface soils with elevated concentrations of <sup>239/240</sup>Pu and/or <sup>241</sup>Am identified during the OU2 RFI/RI including:

Site Characterization Report for the	Document Number:	RF/RMRS-99-427.UN
903 Drum Storage Area,	Revision:	0
903 Lip Area, and Americium Zone	Date:	September 28, 1999
	Page:	16 of 109

- The 35 HPGe measurements which exhibit elevated (above 10 pCi/g) <sup>241</sup>Am activities:
- The area directly below the culvert which drains the 903 Pad and Lip Area where sediments are deposited during surface runoff events; and
- The five 2.5-acre plots where surface soils exceed Tier I RSALs.

The HPGe system used to perform in situ measurements for the investigation employs the Canberra In Situ Object Counting System (ISOCS) software. In order to estimate counting efficiencies, this software requires the entry of various parameters which should accurately represent the actual field conditions at the site. One important parameter is the distribution of contaminants vertically. In the HPGe investigation area, contamination was deposited via airborne and/or surface water releases. This resulted in a distribution with high activities near the surface and decreasing activities with depth, which may follow an exponential function. Surface soil sampling was previously performed in the study area to determine the vertical distributions. In general, the radionuclides are concentrated in the top 5-cm. Based on available data, the ISOCS model assumes all contamination is contained in the top 5-cm, and it is distributed with 66% in the top 3-cm and 33% in the next 2-cm. This distribution was used to be consistent with the surface soil sampling methodologies (RMRS, 1998a), which specifies sampling surface soil to a depth of two inches (5 cm). In addition, the contribution from <sup>241</sup>Am below a depth of 5 cm in soil is quite small. It is possible that the actual distributions in the top 5-cm may be more concentrated near the surface or more uniformly distributed throughout the 5-cm layer. A set of efficiencies with different vertical distributions was prepared and the standard acquisition analyzed.

#### Results:

Default 2 layer 0-3 cm 66%, 3-5 cm 33%	$^{241}$ Am = 12.2 pCi/g
Single layer, 0-5 cm uniform	$^{241}$ Am = 14.3 pCi/g
3 layers, 0-1.5cm 50%, 1.5-3 cm 30%, 3-5 cm 20%	$^{241}$ Am = 11.6 pCi/g
3 layers, default with 1cm grass cover	$^{241}$ Am = 13.2 pCi/g
2 layer with 0-3 cm 60%, 3-5 cm 40%	$^{241}$ Am = 12.2 pCi/g

As can be seen, the overall error of a likely range of possible distributions is about +/- 10 %.

## 2.2.2 Double Sampling Correlation Technique

To "standardize" the *in situ* method, a double sampling technique was employed whereby soil samples were collected from select HPGe measurement locations (RMRS, 1998a) and analyzed in the laboratory for <sup>241</sup>Am, <sup>239/240</sup>Pu, <sup>233/244</sup>U, <sup>235</sup>U, and <sup>238</sup>U using alpha spectroscopy, and <sup>241</sup>Am and <sup>235</sup>U using gamma spectroscopy. [The gamma spectroscopy data was collected by the laboratory to simply "validate" the alpha spectroscopy results, and the two sets of results are comparable as indicated by their linear relationship with a slope of one [(Table 2-1) (Figure 2-2)].

Table 2-1 Laboratory Gamma Spectroscopy Results vs. Laboratory Alpha Spectroscopy Results – <sup>241</sup>Am

HPGe Measurement Location	Laboratory Gamma Spectroscopy Results <sup>241</sup> Am (pCl/g) dry wt	Laboratory Alpha Spectroscopy Results <sup>241</sup> Am (pCl/g) dry wt
30*	3.67	3.67
104	19.08	27.80
265	45.46	49.32
266	21.89	22.60
305	7.45	11.05
406	107.86	77.27
460*	111.09	148.23
669*	57.84	57.85

<sup>\*</sup> Real and Duplicate Sample Results Averaged

In order to acquire a good double sampling correlation over the anticipated range of <sup>241</sup>Am activities, eight HPGe measurement locations were selected that encompass five <sup>241</sup>Am activity intervals; 0-10 (three measurements), 10-20, 20-50 (two measurements), 50-100, and 100-200 pCi/g. These intervals were selected based on detection frequencies of <sup>241</sup>Am activities measured in surface soil samples collected in support of the OU2 Phase II RFI/RI (DOE, 1995; RMRS, 1998a).

Multiple HPGe measurements were taken at some of the double sampling locations for quality control. These results are provided in Table 2-2. In these cases, the measurements at each double sampling location were averaged to create the HPGe data set used in the correlation. Table 2-2 also indicates the HPGe measurements at each double sampling location are relatively uniform.

Fifteen (15) grab samples were then collected at each double sampling location; one grab sample from the center; four grab samples collected at 1- m radius, and ten grab samples from 3-m radius. Figure 2-3 provides this surface soil sampling geometry which was developed by the DOE (DOE, 1997) at the Fernald Environmental Management Project site in Ohio in order to correlate HPGe results to surface soil results. The 1-m and 3-m radius grab samples were then composited into a 1-m and 3-m sample representative of each individual band. Therefore, three separate alpha (and gamma) spectroscopy analyses were performed at each double sampling location.

Samples were collected in this "bulls eye" pattern to mimic the averaging done by the field HPGe detector over the instrument's FOV. The HPGe detector receives gamma-ray photons from every point within the circle; however, it receives more gamma rays from soil closer to the detector than from soil further from the detector. If the circle is divided into concentric bands, the relative weighting factor for each band can be calculated based upon the percentage influence of gamma photons at the detector which originates from a given band of soil, assuming a uniform source distribution with depth and a one MeV photon energy. The relative weighting factor is the relative importance of each band with respect to the probability of gamma-rays emitted from within that band being detected by the HPGe (Table 2-3). The sample results were multiplied by the weighting factor per band, then the products were summed to determine the activity of the soils in the FOV area. Tables 2-4 and 2-5 provide the results of these calculations, including adjustment for moisture content in order to report results on a wet weight or "in situ moisture" basis. Note that if field duplicate samples were collected at a given double sampling location, the "real" and "duplicate" data were averaged (denoted as "combined"), and the "combined" data were used in the weighted averaging process to develop the data for the correlation.

# 2.2.2.1 Alpha Spectroscopy/HPGe <sup>239/240</sup> Pu and <sup>241</sup>Am Correlations

The linear regressions (using the method of least squares) between the alpha spectrometry data (<sup>239/240</sup>Pu and <sup>241</sup>Am) and the HPGe data (<sup>241</sup>Am) show very high degrees of correlation (Figures 2-4 and 2-5). The correlation coefficients (R) are greater than or equal to 0.97. The <sup>241</sup>Am (alpha spectrometry) to <sup>241</sup>Am (HPGe) correlation has a slope (1.25) near 1.0 and a small intercept (4.43 pCi/g) near zero as would be expected when correlating the activities of the same radionuclide.

Site Characterization Report for the	Document Number:	RF/RMRS-99-427.UN
903 Drum Storage Area,	Revision:	. 0
903 Lip Area, and Americium Zone	Date:	September 28, 1999
	Page:	25 of 109

The <sup>239/240</sup>Pu (alpha spectrometry) to <sup>241</sup>Am (HPGe) correlation has a slope of 8.08 which is within the expected range of <sup>239/240</sup> Pu to <sup>241</sup>Am activity ratios considering the in-growth of <sup>241</sup>Am in weapons grade plutonium over 30 to 40 years (elapsed time since the release). The intercept (3.24 pCi/g) is also small in magnitude. These results indicate the regression lines are appropriate models to correlate HPGe data to alpha spectrometry data.

However, according to the SAP (RMRS, 1998a), the 95% upper confidence limits (UCL) of the linear regressions are to provide the equations to calculate the activities of these isotopes in the surface soils at all *in situ* measurement locations (see Figures 2-4 and 2-5). Examination of the results from using the 95% UCL to determine RSAL exceedances strongly suggest this alternative "model" to be overly conservative. Figures 2-6, 2-7, and 2-8 show RSAL exceedances in surface soils in the Americium Zone based on the direct HPGe results<sup>1</sup>, the least square regression lines ("best fit" lines), and the 95% UCL equations for the "best fit" lines, respectively. Also plotted on these figures are RSAL comparisons for historical surface soil data (0-2 inches) from the OU2 RFI/RI trenching investigations (DOE, 1995) and a surface soil investigation conducted by the Actinide Migration Evaluation Project (RMRS, 1998f). These figures also provided RSAL comparisons for the alpha spectrometry results of surface soil samples collected at the eight double sampling locations for this investigation. Analytical results and RSAL comparisons for these surface soil samples are provided in Tables 2-6, 2-7, and 2-8.

As would be expected, Figures 2-6, 2-7, and 2-8 indicate progressively higher actinide levels in surface soils, i.e. increasing numbers of Tier I, and in particular, Tier II RSAL exceedances. As can be seen, the "best fit" line results (Figure 2-7) are substantiated by the historical data. For example, unlike the HPGe "direct" results (Figure 2-6), the Tier II exceedances plotted using the "best fit" line (Figure 2-7) extend to the south bordering on location TR09 (a Tier II exceedance),

<sup>&</sup>lt;sup>1</sup> Because <sup>239/240</sup> Pu is not measured directly by the HPGe instrument at low levels, the <sup>239/240</sup> Pu data used to determine RSAL exceedances was estimated using the <sup>239/240</sup> Pu to <sup>241</sup>Am activity ratio of 5.8 derived from the slope of the regression line (Figure 2-9) for the <sup>239/240</sup> Pu and <sup>241</sup>Am alpha spectroscopy results from the surface soil samples collected at the eight double sampling locations (using real and duplicate sample results).

	Page:	29 of 109

and extend to the east encompassing locations TR12 and AME 5398 (also Tier II exceedances). Also, unlike the 95% UCL results (Figure 2-8), the "best fit" results (Figure 2-7) indicate actinide levels below Tier II to the north at HPGe Measurement Location 30, to the east at HPGe Measurement Location 305, and southeast at TR11. Thus, RSAL exceedances for the "best fit" line (Figure 2-7) are most consistent with the historical and the alpha spectroscopy data, and the best fit line is the chosen model to standardize the HPGe results.

# 2.2.2.2 Alpha Spectroscopy/HPGe <sup>235</sup>U, <sup>238</sup>U Correlations

As shown in Figures 2-10 and 2-11, correlations for the alpha spectrometry/HPGe data for <sup>235</sup>U and <sup>238</sup>U were not performed because in both cases the uranium isotopes were not detected by *in situ* HPGe. The plots show minimum detectable activities when the isotopes were non-detected. Also, alpha spectrometry did not measure detectable levels of <sup>235</sup>U, and only in a few instances was <sup>238</sup>U detected at estimated activities. Therefore, <sup>235</sup>U and <sup>238</sup>U results from the HPGe survey in the Americium Zone were used directly as the surface soil radiological data for these isotopes. The lack of correlation for the uranium data does not impact the findings reported herein because the activities of uranium isotopes are well below the Tier II RSALs throughout the investigation area.

The activity of <sup>233/234</sup>U was calculated based on the fact that <sup>234</sup>U should be in equilibrium with <sup>238</sup>U (the activity contribution of <sup>233</sup>U is insignificant). The equilibrium between the radioactive parent (<sup>238</sup>U) and daughter (<sup>234</sup>U) suggests the activity ratio between these two isotopes should be 1.0. Surface soil data collected in support of the OU2 Phase II RFI/RI supports this relationship with an average activity ratio of 0.97 between the two isotopes. Therefore, the activity of <sup>233/234</sup>U in surface soil was assigned the value measured by the HPGe survey for <sup>238</sup>U.

# 2.2.3 FIDLER Surveys

A FIDLER survey was conducted in a selected area where an isolated HPGe measurement exceeded the 10 pCi/g <sup>241</sup>Am decision level. The FIDLER survey was conducted at HPGe measurement location 301 to determine if the measurement result was caused by the presence of a smaller area containing a hot spot. In addition, two FIDLER surveys were conducted at HPGe measurement locations 460 and 462 where HPGe measurements exceeded the RFCA Tier I

Site Characterization Report for the	Document Number:	RF/RMRS-99-427.UN

903 Lip Area, and Americium Zone	Date:	September 28, 1999
	Page:	30 of 109

RSALs based on preliminary results using the sum-of-ratios methodology. The purpose of the survey was to determine whether contamination was homogeneous and widespread as suggested by the conceptual model, or heterogeneous and consists of numerous individual hot spots.

A grid with four-foot spacings was staked in the field to encompass the circular FOV for the HPGe measurement. A total of 37 FIDLER measurements were collected from each selected HPGe measurement location. FIDLER measurements were taken with the instrument placed on the ground surface at each of the four-foot grid nodes for a one-minute count. FIDLER surveys were conducted in accordance with Radiological Safety Procedure, 3-PRO-112-RSP-2.01, Job Aid: 4-JOB-010-RSP-02.01.07, Bicron FIDLER (Kaiser-Hill, 1999b).

#### 2.3 SUBSURFACE SOIL INVESTIGATION

The subsurface soil investigation consisted of two phases. One phase was the radiological investigation consisting of shallow boreholes. The second phase consisted of the VOC investigation.

# 2.3.1 Radiological Investigation

Subsurface soil sampling for radiological characterization was conducted at the 903 Pad and Lip Area. The depth of radiological contamination is required to estimate the volume of soil requiring remedial action. Figure 2-12 provides the radiological subsurface sampling locations for the 903 Pad and Lip Area. Samples were analyzed for <sup>241</sup>Am, <sup>239/240</sup>Pu, <sup>233/244</sup>U, <sup>235</sup>U, and <sup>238</sup>U using alpha spectrometry. Boring logs are presented in Appendix A.

903 Pad - Twenty-five shallow boreholes were drilled for the characterization of radionuclide contamination beneath the 903 Pad. Twenty-five boreholes over the 3.4-acre 903 Pad represents a borehole completed at each node of a 23 m by 23 m (75 ft by 75 ft) grid (Figure 2-12). Subsurface soil samples were collected from artificial fill material and natural soils beneath the 903 Pad for radiochemical analysis utilizing a single-tube Geoprobe hydraulic push drilling technique. Soils were continuously cored to a total depth of approximately 1.2 m (4 ft) to ensure core recovery or to a depth where the FIDLER indicated less than 5,000 cpm. Samples were

Site Characterization Report for the	Document Number:	RF/RMRS-99-427.UN
903 Drum Storage Area,	Revision:	0
903 Lip Area, and Americium Zone	Date:	September 28, 1999
	Page:	31 of 109

collected at approximately 15 cm (6 in) intervals or as appropriate so that the sample intervals coincide with asphalt, artificial fill material, and natural soils. This was done to prevent potential dilution of the natural soil samples below the artificial fill material. Borings and core were checked by engineer's tape for total depth and recovery. Samples for radiological screening were collected as a composite sample from the radiological sample. Soil samples were screened for alpha, beta/gamma, and VOCs using portable field instruments. If VOCs were detected above 10 parts per million by field instrumentation at any sampling location, the VOC subsurface soil sampling program, as described in the SAP (RMRS, 1998a), was implemented to characterize VOC contamination at that location.

Subsurface soil samples for radiochemical analysis were also collected during the VOC subsurface investigation as described in Section 2.3.2. Soil samples were collected from 12 original and three "step-out" boreholes on the 903 Pad, one borehole west of the 903 Pad, and one borehole east of well 07191 in the Lip Area (see Figure 2-13).

Lip Area - A total of thirty-seven boreholes were completed over the Lip Area where artificial fill was placed in 1970 and where surface soils were remediated in 1976, 1978, and 1984. Of the 37 boreholes, 25 borings were original and twelve were "step-out" borings (Figure 2-12). Of the 37 boreholes, two boreholes were completed in the 1976 remediation area, six boreholes were completed in the 1978 remediation area, and three boreholes were placed in the 1984 remediation area.

Shallow soil borings located in the 903 Lip Area and soil samples were collected utilizing single-tube Geoprobe hydraulic push drilling technique. Soils were continuously cored to either a total depth of 0.9 m (3 ft) or 1.2 m (4 ft) to ensure core recovery, or to a depth where the FIDLER indicated less than 5,000 cpm. Samples were collected at approximately 15 cm (6 in) intervals or as necessary so that the sample intervals coincide with artificial fill material and natural soils. This was done to prevent potential dilution of the natural soil sample below the artificial fill material. Borings and core were checked by engineer's tape for total depth and recovery. Samples for radiological screening were collected as a composite sample from the radiological sample. Soil samples were screened for alpha, beta/gamma, and VOCs using portable field instruments.

	Page:	32 of 109

A detailed surface soil characterization using HPGe was not performed in portions of the Lip Area where surface/subsurface soils were collected (RMRS, 1998a).

#### 2.3.2 VOC Investigation Boreholes

Investigation of VOC contamination at the 903 Pad, completed per the SAP (RMRS, 1998a), targeted the highest areas of groundwater contamination as well as the anomalous PCE soil gas results, east of groundwater well 07191. Figure 2-13 shows the borehole locations for the VOC investigation. Samples were analyzed for <sup>241</sup>Am, <sup>239/240</sup>Pu, <sup>233/244</sup>U, <sup>235</sup>U, and <sup>238</sup>U using alpha spectroscopy and for VOCs using EPA Method 8260B (EPA, 1986). Boring logs are presented in Appendix A.

Subsurface soil sampling was conducted near existing groundwater monitoring wells 06691, and 08891 using an upgradient radial placement geometry with the well location serving as the downgradient location. Boreholes were located approximately 20 ft to the north, south, and west of well locations 06691, and 08891. Six boreholes were placed along the west to northwest side of the 903 Pad on the basis of aerial photographs showing drum storage and surface staining. A total of 15 boreholes were required to investigate the VOC contamination at the 903 Pad, the original 12 boreholes, two "step-out" boreholes (95998 and 97698), and one completion of a shallow subsurface radiological borehole (90998) as a VOC borehole (96498) where VOCs were observed with concentrations greater than 10 percent of the respective current Tier I SSALs.

The soil gas anomaly in the Lip Area at the southeast corner of the 903 Pad adjacent to well 07191 was evaluated. One borehole (97298) was located 20 ft east and 10 ft south of well 07191. A surface area with little or no vegetation and FIDLER readings greater than 10,000 cpm was identified 30 feet east of well 6591, adjacent to the west side of the 903 Pad. One borehole (92598) was completed to evaluate this area.

Soil samples were collected from VOC soil borings located in the 903 Pad and Lip Area utilizing a dual-wall Geoprobe hydraulic push drilling technique. Boreholes were advanced from the surface to either a depth of 0.31 to 0.62-m (1 to 2 feet) below the top of bedrock, or to a depth below the vertical extent of VOC contamination (based on field instruments), whichever was

Site Characterization Report for the	Document Number:	RF/RMRS-99-427.UN
903 Drum Storage Area,	Revision:	0
903 Lip Area, and Americium Zone	Date:	September 28, 1999
	Page:	33 of 109

greater, provided refusal of the Geoprobe drilling equipment was not encountered. Samples were collected at approximately 1.22-m (4 ft) intervals below ground surface, or at intervals where VOCs were detected with field instrumentation. In general, the VOC samples were collected from approximately the lower 15-cm (6 in) interval and the radiological sample was collected from the 15-cm (6 in) interval above the VOC sample. Samples for radiological screening were collected from the 15-cm (6 in) interval above the radiological sample. Because of the different ionization potential between PCE and CCl<sub>4</sub>, two photoionization detectors were used (10.4 and an 11.7 electron volt bulb). If VOCs were detected above 10% of the current Tier I SSALs, then the sampling grid was extended an additional 6.1-m (20 ft) in an upgradient direction of that location, and additional samples were collected for laboratory analysis.

#### 2.4 903 PAD ASPHALT SAMPLES

Asphalt samples from the 903 Pad were collected to obtain preliminary waste characterization data for disposal purposes. Nine asphalt samples were collected randomly from the following locations over the 903 Pad: 90098; 90198; 90398; 90698; 90798; 91198; 91298; 91898; and 91998 (Figure 2-12). Random sampling techniques are appropriate methods for estimating the population mean and the standard error of this estimate. Locations were determined randomly based on the 903 Pad subsurface soil sampling grid. Samples were collected using a Geoprobe® and analyzed for <sup>241</sup>Am, <sup>239/240</sup>Pu, <sup>233/234</sup>U, <sup>235</sup>U, and <sup>238</sup>U using alpha spectroscopy.

# 2.5 WORK CONTROLS

Field activities were conducted in accordance with the procedures detailed in the SAP (RMRS, 1998a), the Task-Specific Health and Safety Plan (RMRS, 1998b) and additional controls summarized herein. Additional work controls implemented for the project included the ALARA Job Review (#903Pad-98-001) for fieldwork performed under job-specific Radiation Work Permits (RWPs). Contamination control included measurement of direct and removable contamination levels on equipment, wind speed monitoring (soil handling activities suspended with two consecutive 15-minute wind speed average of 15 miles per hour), high volume air sampling during soil handling activities, and requirements for personal protective equipment. Fieldwork also could not be performed due to sensitivity of the radiological field instruments

# 3.0 DATA QUALITY ASSESSMENT

This section provides the results of the data quality assessment that was conducted in accordance with the Evaluation of Data for Usability in Final Reports (RMRS Procedure, ER/RMRS-98-200 [RMRS, 1998c]). This assessment ensures that data used in making management decisions for remedial actions is of adequate quality to support the decisions.

As discussed herein, Data Quality Objectives for the project were achieved. A summary of project DQOs and the corresponding project decisions is presented in Table 3-1.

Table 3-1 Sample Types & Data Quality Objectives

Sample Type	DQO	Decision
Actinides in Surface Soils using <i>In Situ</i> Gamma Spectroscopy.	Quantify spatial distribution of RFETS actinide activities that meet or exceed Tier I RSALs to estimate soil volumes requiring remediation. Quantify spatial distribution of <sup>241</sup> Am to 10 pCi/g using HPGe gamma ray survey.	Spatial extent of actinide activities exceeding Tier I RSALs. Volume estimates of soils exceeding Tier I and Tier II RSALs.
VOCs in Subsurface Soils.	Quantify three-dimensional distribution of VOC concentrations that meet or exceed Tier I Soil Action Levels to estimate soil volumes requiring remediation.	Three-dimensional extent of VOC concentrations relative to Tier I soil action levels. Volume estimates of soils exceeding Tier I soil action levels.
Actinides in Subsurface Soils.	Quantify three-dimensional distribution of actinides to estimate soil volumes requiring remediation.	Three-dimensional extent of actinide activities relative to Tier I & II RSALs. Volume estimates of soils exceeding Tier I and II RSALS.

# 3.1 VERIFICATION OF RESULTS

Verification ensures that data produced and used by the project are documented and traceable per quality requirements. Generally, verification consists of reviewing the data to determine whether:

- Chain-of-Custody was intact from initial sampling through transport and final analysis;
- Preservation and hold-times were within tolerance;
- Selected samples underwent analysis at certified labs; and
- Format and content of the data is clearly presented relative to goals of the project.

Site Characterization Report for the	Document Number:	RF/RMRS-99-427.UN
903 Drum Storage Area,	Revision:	0
903 Lip Area, and Americium Zone	Date:	September 28, 1999
	Page:	49 of 109

In addition to the criteria noted above, verification of the data also included additional checks sometimes acknowledged as within the "validation" category, depending on the type of analysis:

- Surrogate recovery;
- MS/MSD recovery;
- Calibrations;
- · Blanks;
- Sample preparations; and
- Other quality control.

In order to provide an integrated evaluation of the data quality, results of the verification are collectively discussed with validation in Section 3.2.

#### 3.2 VALIDATION

Validation consists of a technical review of the data, or portion of the data, so that any limitations of the data relative to project goals are identified, and the associated data are qualified accordingly. Data were validated relative to the precision, accuracy, representativeness, completeness, and comparability (PARCC) parameters described in the next section. K-H Analytical Services Division also currently performs validation on a site-wide basis at 25% frequency. Satisfactory validation at this frequency indicates that the subcontracted labs are operating competently relative to industry-wide standards, and more specifically, that sample custody and analytical procedures are implemented under defined quality controls. Site-wide data validation coupled with annual lab audits provides the inference that all analytical and radiochemical results not specifically validated, are represented by the percentage that is validated.

Validation by an independent third party was performed on 37 percent of the alpha spectroscopy data and 32 percent of the VOC data, which exceeded the requirement of 25 percent validation by an independent third party. The remaining alpha spectroscopy and VOC data were verified by an independent third party. Original verification and validation (V&V) packages for the project are managed and filed by the K-H Analytical Services Division, Building 881.

Site Characterization Report for the	Document Number:	RF/RMRS-99-427.UN
903 Drum Storage Area,	Revision:	0
903 Lip Area, and Americium Zone	Date:	September 28, 1999
·	Page:	50 of 109

Verification and validation of the project data, summarized in Sections 3.1 through 3.3, included use of the following protocols and guidance:

- RMRS Procedure RF/RMRS-98-200, Evaluation of Data for Usability in Final Reports (RMRS, 1998c);
- USEPA Contract Laboratory Program National Functional Guidelines for Inorganic Data Review, EPA 540/R-94/013, (EPA, 1994b);
- USEPA Contract Laboratory Program National Functional Guidelines for Organic Data Review, EPA 540/R-94/012, (EPA, 1994a);
- Guidance for Data Quality Assessment, Practical Methods for Data Analysis, EPA QA/G-9, (EPA, 1996b);
- Kaiser-Hill Team Quality Assurance Program, Rev. 5, (K-H, 1997); and
- RMRS Quality Assurance Program Description (QAPD), RMRS-QAPD-001, Rev. 2, (RMRS, 1998d).

#### 3.3 PARCC PARAMETERS

#### 3.3.1 Precision

Precision is a measure of the reproducibility of results. Precision is evaluated by comparing results from field duplicate and/or replicate (duplicate/replicate) samples with results from associated real samples. Precision was evaluated quantitatively by using two functions, relative percent difference (RPD), and duplicate error ratio (DER), where the latter function is used to account for the stochastic nature of error of radioactivity.

Equations 3.1 and 3.2 present the RPD and DER equations

RPD = 
$$\frac{|C_1 - C_2|}{|(C_1 + C_2)/2|}$$
 (Eq. 3.1)

where:

C<sub>1</sub>=Concentration of the analyte in the real sample C<sub>2</sub>=Concentration of the analyte in the duplicate sample

Site Characterization Report for the	Document Number:	RF/RMRS-99-427.UN
903 Drum Storage Area,	Revision:	0
903 Lip Area, and Americium Zone	Date:	September 28, 1999
•	Page:	51 of 109

$$|C_1 - C_2|$$
DER = 
$$\frac{|C_1 - C_2|}{\sqrt{(TPU^2_{C1} + TPU^2_{C2})}}$$
where:
$$TPU = \text{total propagated uncertainty}$$
(Eq 3.2)

#### Duplicate/Replicate Sample Collection Methodology

Field duplicate samples collected in support of the surface soil programs were collected as unique samples. The duplicate samples were generated from grab samples of surface soils collected at HPGe measurement locations. The duplicate samples were collected adjacent to the real samples collected over the same HPGe FOV, composited, and placed into sample jars. Replicate and real samples of subsurface soils collected for alpha spectroscopy analysis were generated by splitting the recovered core in half lengthwise. VOC quality control (QC) samples are identified as duplicates because the real and QC samples were collected from adjacent depth intervals (i.e. not split).

The purpose of the field duplicate and replicates are to evaluate the precision of the field sampling process. The QC criterion for RPDs is  $\leq 40\%$ , and for DERs the criterion is  $\leq 1.96$ . Individual RPDs/DERs can be found in Appendix B. Duplicate/replicate samples exceeding the DER QC criterion of 1.96 are interpreted as different at the 5% level of significance. Duplicate/replicate samples exceeding the RPD QC criterion of 40%, indicate that precision does not comply with DQO specifications, and require an explanation and justification for deficiencies, and a determination if additional sampling is required. At least 85% of all quality control samples are required to comply with the established precision or RPD goals. The following sections describe the results of duplicate/replicate sample results for each laboratory analytical program.

#### In Situ Gamma Spectroscopy (HPGe) Program

The gamma spectroscopy unit collected a total of 1,110 in situ measurements. The required frequency of duplicate samples was one measurement for each set of 20 real measurements. A total of 58 duplicate measurements were collected (1 in 19.1) meeting the required collection frequency. All 58 duplicate measurements acquired were within error tolerances (DER  $\leq$  1.96) for <sup>241</sup>Am. This excellent performance by the *in situ* system indicates the large-area, physical-

Site Characterization Report for the	Document Number:	RF/RMRS-99-427.UN
903 Drum Storage Area,	Revision:	0
903 Lip Area, and Americium Zone	Date:	September 28, 1999
	Page:	52 of 109

averaging is a repeatable method. Appendix B provides the TPU for HPGe measurements used in the DER calculations.

#### Laboratory Gamma Spectroscopy

A total of 24 real and nine duplicate surface soil samples (1 in 2.7) from three double sampling HPGe measurement locations were provided to the laboratory for gamma spectroscopy analysis for <sup>241</sup>Am. The frequency for duplicate sample collection for gamma spectroscopy analysis was met for this program. <sup>241</sup>Am activities were detected above the method detection limit in all samples. As shown in Table 3-2 two of the nine duplicate samples failed DER tolerances for an overall precision of 78%. Because DERs were calculated using the laboratory instrument's counting error as the only source of TPU, this overall precision is considered acceptable.

Table 3-2 Surface Soil Duplicate Assessment – Gamma Spectroscopy Results

Analyte	Total Real Samples Collected	Total Duplicates Collected	Number of Duplicates within DER	Overall Precision Compliance
<sup>241</sup> Am	24	9	7	78%

#### Laboratory Alpha Spectroscopy

As indicated in this section, the precision results for <sup>241</sup>Am and <sup>239/240</sup>Pu did not meet the project goal of 85% compliance. However, as discussed subsequently, the precision results do not compromise the objectives of the investigation.

#### Surface Soils

A total of 24 real and nine duplicate surface soil samples were collected from three double sampling HPGe measurement locations and were provided to the laboratory for alpha spectroscopy analysis for <sup>241</sup>Am, <sup>239/240</sup>Pu, and uranium isotopes. The frequency for duplicate sample collection for alpha spectroscopy analysis was met for this program. <sup>241</sup>Am activities were detected above the method detection limit in all samples. As shown in Table 3-3 eight of the nine duplicates failed DER tolerances for <sup>239/240</sup>Pu with an overall precision compliance of 11%. Five of the nine duplicates failed DER tolerances for <sup>241</sup>Am with an overall precision compliance of 44%. Uranium isotopes met the project's precision compliance goal. As with the laboratory

903 Drum Storage Area,	Revision:	0
903 Lip Area, and Americium Zone	Date:	September 28, 1999
	Page:	53 of 109

gamma spectroscopy, DERs were calculated using the laboratory instrument's counting error as the only source of TPU.

Table 3-3 Surface Soil Duplicate Assessment - Alpha Spectroscopy Results

Analyte	Total Real Samples Collected	Total Duplicates Collected	Number of Duplicates within DER	Overall Precision Compliance
<sup>239/240</sup> Pu	24	9	1	11%
<sup>241</sup> Am	24	9	4	44%
233/234 U	24	9	8	89%
<sup>235</sup> U	24	9	9	100%
<sup>238</sup> U	24	9	8	89%

# Subsurface Soils

A total of 349 real and nineteen replicate surface and subsurface soil samples and asphalt samples were collected from boring locations and were provided to the laboratory for alpha spectroscopy analysis for <sup>241</sup>Am, <sup>239/240</sup>Pu, and uranium isotopes. The frequency for replicate sample collection (1 in 18.5) for alpha spectroscopy analysis was met for this program. As shown in Table 3-4, ten of the replicates failed DER tolerances for <sup>239/240</sup>Pu for an overall precision compliance of 44%. Six of the nineteen samples failed DER tolerances for <sup>241</sup>Am for an overall precision compliance of 68%. All uranium isotopes met the project's precision compliance goal. Again, DERs were calculated using the laboratory instrument's counting error as the only source of TPU.

Table 3-4 Radionuclide Subsurface Soil Replicate Assessment – Alpha Spectroscopy Results

Analyte	Total Real Samples Collected	Total Replicates Collected	Number of Replicates within DER	Overall Precision Compliance
<sup>239/240</sup> Pu	349	19	9	47%
<sup>241</sup> Am	349	19	13	68%
233/234 U	349	19	19	100%
<sup>235</sup> U	349	19	19	100%
<sup>238</sup> U	349	19	. 18	95%

	Page:	54 of 109

#### Discussion

One source of the apparent imprecision of the radionuclide data may be attributed to the exclusion of sources of uncertainty beyond the instrument counting error. The DER calculation incorporates TPU that includes all uncertainties introduced from sample collection in the field through radiological analysis. However, the only uncertainty included in the TPU for this data quality assessment is the counting error at the 2-sigma level. This reduction in uncertainty in the TPU term leads to an exaggerated number of samples exceeding the DER of 1.96.

Secondly, when comparing the gamma and alpha spectroscopy DER results there appears to be an increased error associated with analyzing only an aliquot (0.25 to 2.0 grams) of the sample using alpha spectroscopy versus analyzing the entire sample (gamma spectroscopy). The overall precision for <sup>241</sup>Am using gamma spectroscopy was 78% compared to 44% for alpha spectroscopy. Since the duplicate samples were collected from the same locations as the samples analyzed using gamma spectroscopy, a significant portion of difference in overall precision for <sup>241</sup>Am between these two methods may be attributed to the heterogeneous distribution of <sup>241</sup>Am on a small scale, as exemplified by this comparison.

This heterogeneity is also obvious by comparing the surface soil "duplicate" sample results (Table 3-3) to the subsurface soil "replicate" sample results (Table 3-4). As can be seen from the subsurface sample program, the overall precision of "replicate" samples for <sup>241</sup>Am and <sup>239/240</sup>Pu (47% and 68%, respectively) are higher than the overall precision of "duplicate" samples (<sup>241</sup>Am at 11% and <sup>239/240</sup>Pu at 44%). "Duplicate" samples were unique samples collected from adjacent locations whereas "replicate" samples for subsurface soils were splits from the same recovered core. The heterogeneous distribution of <sup>241</sup>Am and <sup>239/240</sup>Pu activities in surface soils is evident at these small intersample distances. Heterogeneity is also observed in the FIDLER survey results (Section 4.1.3).

Although it is clear that micro-scale heterogeneous distributions exist for <sup>241</sup>Am and <sup>239/240</sup>Pu activities in surface soil, the high degree of correlation between the lower precision alpha spectroscopy results and the higher precision HPGe gamma spectroscopy results indicate insignificant impact to the regression "model". With respect to subsurface soils, the distributions

Site Characterization Report for the	Document Number:	RF/RMRS-99-427.UN
903 Drum Storage Area,	Revision:	0
903 Lip Area, and Americium Zone	Date:	September 28, 1999
	Page:	55 of 109

of <sup>241</sup>Am and <sup>239/240</sup>Pu activities do not indicate patterns anomalous to those expected from the site conceptual model and/or historical data.

#### Volatile Organic Compound Analysis (EPA 8260B)

A total of 86 real and five duplicate subsurface soil samples (1 in 17.2) were collected and provided to the laboratory for analysis of VOCs. Therefore, the frequency for duplicate sample collection for VOC analysis was met for this program. Table 3-5 provides the number of samples collected under this program and the results of the RPD for the duplicate assessment. One sample pair detected VOCs in both the duplicate and associated real sample. The four other RPD calculations were conducted on sample pairs that had VOC detections in the real samples but not in the associated duplicate sample. The method detection limit was used in RPD calculations when no detections were found in the duplicate sample. Overall precision compliance for the VOC investigation was 60% where two of five duplicate sample sets were observed to exceed the RPD of 40%. Although the relative percent differences in concentrations between the real duplicate samples for each of these analytes may be significant, the detected concentrations are all well below their respective current RFCA Tier I soil action levels, i.e. because of the relatively low magnitudes of the concentrations, imprecision does not affect overall project decisions relative to VOC contamination.

Table 3-5 Duplicate Sample Assessments – Volatile Organic Compound Analysis

Analyte	Total Real Samples Collected	Total Duplicates Collected	Number of Duplicates within RPD	Overall Precision Compliance
PCE	86	5	3	60%
TCE	86	5	3	60%
CCL₄	86	5	4	80%
1,2-DCE	86	5	3	60%

Although the overall precision compliance is less than project completeness goals, precision of the VOC results is acceptable. The apparent imprecision noted is limited to values well below the Tier I soil action levels (i.e., between detection limits and 10% of Tier I soil action levels), and, as such, does not impact project decisions relative to nature and extent of VOC contamination in the soil.

Site Characterization Report for the	Document Number:	RF/RMRS-99-427.UN

# 3.3.2 Accuracy

Accuracy is a measure of how closely an analytical or survey result corresponds to the true concentration or activity in a sample. Systematic uncertainties that affect accuracy, also known as bias, are also discussed in this section.

#### In Situ Gamma Spectroscopy

The accuracy of *in situ* gamma spectroscopy is corroborated through two methods of validation implemented for the project: systematic validation, and more importantly, performance validation, that is, through the use of comparing and correlating surface soil samples analyzed by laboratory alpha spectroscopy. The quality of the correlation, which exhibited a high correlation coefficient for linearity (Figure 2-5), validate the entire gamma spectroscopy measurement system relative to the site-specific matrix types and radiological levels of interest.

The systematic validation of gamma spectroscopy results yielded no significant qualifications to the data. Detailed technical considerations and their effects on data quality are further detailed in the Appendix C under "903 Pad In-Situ Models and Uncertainties".

Another measure of accuracy is determined by comparing the detection limit proposed to the actual detection limit reported for the sample results. Table 3-6 provides a comparison of detection limits for the *In Situ* Gamma Spectroscopy program.

Table 3-6 Comparison of Detection Limits – In Situ Gamma Spectroscopy

Analyte	Required Analytical Method	Required Detection Limit (pCi/g)	Actual Detection Limit (pCi/g)
<sup>241</sup> Am	In Situ Gamma Spectroscopy	1.0	0.38 - 1.43
<sup>235</sup> U	In Situ Gamma Spectroscopy	0.5	0.36 - 0.72
<sup>238</sup> U	In Situ Gamma Spectroscopy	5.0	1.31 – 6.49

As can be seen in Table 3-6 the lower limit of the actual detection limit was met for all three radionuclides. The required detection limit was exceeded for <sup>241</sup>Am and <sup>238</sup>U in a limited number

Site Characterization Report for the	Document Number:	RF/RMRS-99-427.UN
903 Drum Storage Area,	Revision:	0
903 Lip Area, and Americium Zone	Date:	September 28, 1999
	Page:	57 of 109

of analyses; however, these exceedances do not significantly impact the results of the HPGe survey nor the resulting volume estimates.

#### Laboratory Alpha Spectroscopy

The accuracy of laboratory alpha spectroscopy data was evaluated with respect to detection limits. Table 3-7 provides a comparison between required detection limits and actual detection limits.

Table 3-7 Comparison of Detection Limits - Alpha Spectroscopy

Analyte	Required Analytical Method	Required Detection Limit (pCi/g)	Actual Detection Limit (pCi/g)
<sup>239/240</sup> Pu	RC01B001	0.3	0.028 - 0.122
<sup>241</sup> Am	RC01B001	0.3	0.0061- 0.168
<sup>233/234</sup> U	RC01B001	1.0	0.015 - 0.472
<sup>235</sup> U	RC01B001	1.0	0.016 - 0.472
238U	RC01B001	1.0	0.008 - 0.643

As can be seen in Table 3-7 the actual detection limit was lower than the required detection limit for all radionuclides. Therefore, accuracy from alpha spectroscopy detection limits were adequate for all sample analyses for decision making purposes.

#### Volatile Organic Compound Analysis (EPA 8260B)

The accuracy of VOC data was evaluated with respect to detection limits. Table 3-8 provides a comparison between required detection limits and actual detection limits.

The method detection limit was revise during the VOC Subsurface Investigation from the midlevel detection limit (740 ug/kg) specified in the SAP (RMRS, 1998b) to a low-level detection limit (5 ug/kg). The required detection limit of 740 ug/kg was exceeded for the target analytes in all samples from boring 96498, and in one sample each from borings 96198 and 96298. The detection limit exceedance in samples from boring 96498 was due to sample analysis using the VOA-CLP, mid level method. However, the actual detection limit is lower than the current Tier I soil action levels for VOCs and therefore did not impact decision making based on current SSALs. Date: September 28, 1999
Page: 58 of 109

Table 3-8 Comparison of Detection Limits - Volatile Organic Compound Analysis

Analyte	Required Analytical Method	Required Detection Limit (ug/kg)	Actual Detection Limit (ug/kg)
Carbon Tetrachloride	8260B	740	5.0 – 1500
Chloroform	8260B	740	0.1 – 1500
Cis-1,2- dichloroetherne	8260B	740	0.1 – 1500
Methylene Chloride	8260B	740	. 1.4 – 1500
Tetracholorethene	8260B	740	0.41 - 1500
Trichloroethene	8260B	740	0.31 - 1500

During review of the data the following biases were noted that cause the data to be qualified. Two other types of QC samples were generated in support of the VOC subsurface soil investigation; equipment rinse blanks and trip blanks. Table 3-9 provides a QC summary for methylene chloride detected in an equipment rinse blank and the associated real samples. Per EPA guidance (EPA, 1989) the methylene chloride detections in the real samples are less than ten times the detection in the associated equipment rinse blank and will be qualified as non-detect. Although trip blanks were submitted and analyzed with real samples, no qualifications were required for the associated real samples.

Methylene chloride was detected at estimated (J) concentrations in 16 samples (0.59 J to 410 J ug/Kg) at less then the method reporting limit. However, the maximum detected concentration in a method blank from the entire sample data set is 860 ug/Kg. Using EPA guidance (EPA, 1989) the concentration in the samples do not exceed ten times the maximum amount detected in any blank. Therefore, methylene chloride detections are considered a result of laboratory contamination.

Acetone was not detected in the associated rinse or method blanks in several samples from boring 97698 (99A8275), however, acetone may not be present in the sample because the continuing calibration verification criteria were not met. Acetone was detected in samples from boring 96398 (99A4102) (ranging from 1,200 up to 3,300 ug/Kg). However, the maximum detected concentration in a method blank from the entire sample data set is 670 ug/Kg. Using EPA guidance (EPA, 1989) the concentration in the samples do not exceed ten times the maximum

903 Drum Storage Area,	Revision:	0
903 Lip Area, and Americium Zone	Date:	September 28, 1999
	Page:	59 of 109

amount detected in any blank. Therefore, acetone detections are considered a result of laboratory contamination.

Table 3-9 Quality Control Sample Summary

QC Sample ID	QC Sample Type	Assoc. Real Sample(s)	Analyte(s) Detected in QC Sample	Detect in Real Samples Associated Method Blank (yes/no)	Comments
99A6650- 007.002	equipment rinse	99A6650- 002.002	Methylene chloride	no	Methylene chloride detections in field
	blank	99A6650- 003.002		no	samples <10 times the detection in the QC
		99A6650- 004.002		no	sample. Result will be qualified as non-detect (U) (EPA, 1989).
		99A6650- 005.002 99A6650-		no	(0) (21 A, 1909).
		006.002		no	

The compound trichlorotrifluoroethane was detected in several samples from borehole 97698 (99A8275). Detections of trichlorotrifluoroethane are not considered repeatable as the dilution results for this sample indicated trichlorotrifluoroethane was no longer present. The results were assigned the J148 qualifier, as the associated value is estimated and the linear range of the measurement system was exceeded. Results were then adjusted with the dilution Contract Required Quantitation Limit and given the qualifier UD, the associated value is considered undetected at an elevated level of detection.

PCE was detected in two samples from boring 95998, at 1,540 ug/kg and 343 ug/kg with an E (estimated) qualifier. When re-analyzed by the lab the PCE results were 3,060 ug/kg and 174 ug/kg, respectively, with a D qualifier (dilution).

Qualifications of VOC data did not affect accuracy or project decision making. VOC samples were analyzed using an expedited turn-around to assist field decisions based on "Form-1's" faxed from the laboratory. Although VOC detection limits varied during the course of the project, the detection limits were lower than the current Tier I soil action levels for VOCs and therefore did not impact decision making based on these action levels.

	Page:	60 of 109

# 3.3.3 Representativeness

Representativeness is evaluated by comparing the number and types of samples identified in the SAP with the number and type of samples actually collected. The number of samples required was based on meeting the DQOs of the characterization. Table 3-10 provides a comparison of planned samples vs. actual samples collected in support of the investigation. Table 3-11 provides a comparison of QC samples and real samples collected for the investigation.

As can be seen from Table 3-10, all areas met or exceeded planned sample requirements with the exception of the HPGe survey in the Lip Area and characterization of the asphalt and fill at the 903 Pad by alpha spectroscopy. Surface soils in the Lip Area were characterized by twenty borings completed during the subsurface radiological program. Sample results collected from the 0-6 inch interval were used to characterize surface soils in this area. Asphalt and fill samples were to be collected at all 25 boring locations within the 903 Pad. This number of samples was later determined to be excessive and the SAP was revised to include the collection of samples at nine randomly selected locations.

As can be seen from Table 3-11, the collection frequency of quality control samples was met for all analytical programs with the exception of trip blanks. Detections of VOCs in soil samples shipped without trip blanks are considered actual detections except where qualified previously as a laboratory contaminant.

#### 3.3.4 Completeness

Completeness is typically expressed as a percentage, calculated as a ratio of usable results to the number of samples collected. One hundred percent of the data were verified at the project level based on comparing usable data with unusable data (RMRS, 1998c). Completeness is 100% exceeding the project's goal of 90%. Additional sampling is not required to meet the project objectives of estimating soil volumes exceeding current action levels and characterizing surface soils to 10 pCi/g <sup>241</sup>Am.

#### Deviations

Despite weather constraints and field activities conducted non-sequentially among the subsurface investigations of the 903 Pad, Lip Area, and the VOC program, quality control samples were collected at a frequency of one in 20 during the entire subsurface investigation. Trip blank samples for VOC samples were reduced to a frequency of one trip blank for every 20 real VOC samples, detections not associated with a trip blank will be considered actual detects. Two of the required VOC trip blank samples were missed. This deviation from the SAP is justifiable as the analytical data is adequate to characterize subsurface soil and thus is representative of the subsurface soil conditions. Gamma spectroscopy analysis of aqueous samples could not be performed on rinse blank water samples. Two of the VOC investigation boreholes were not completed to bedrock due to refusal of the geoprobe sampling equipment at boreholes 96798 and 97698. Data collected from these boreholes are adequate and representative of subsurface soil conditions.

### 3.3.5 Comparability

All results presented are comparable with historical sampling and analyses results. This comparability is based on standard methods (EPA-approved methods), systematic quality controls, and thorough documentation of the planning, sampling, and analysis process.

The comparability of two samples were questioned during the investigation. One sample from HPGe measurement location 104 at 3 meters (98A5590-001.006) was reanalyzed as sample 98A5590-004.001 because <sup>241</sup>Am results from the first analysis were elevated and not comparable to the other sample results collected at this location. One alpha spectroscopy sample result from boring 94298 (98A2014-001.002) was rejected due to the MDA exceeding the RDL. However, sample results are reported high and are comparable to other Native 1 soil radiological results and therefore are usable. The remaining soil samples results are comparable because consistent sample collection activities and analysis were performed in accordance with the SAP (RMRS, 1998) and procedures described in Section 2.0.

Site Characterization Report for the	Document Number:	RF/RMRS-99-427.UN
903 Drum Storage Area,	Revision:	0
903 Lip Area, and Americium Zone	Date:	September 28, 1999
	Page:	64 of 109

# 3.3.6 Sensitivity

Sensitivity was evaluated by comparing actual quantitation limits of the results with the regulatory or project-specific action levels required for decision-making. All analytical and radiological methods achieved adequate sensitivities based on quantitation limits well below regulatory thresholds, typically with a quantitation limit at less than 50% of the threshold.

# 3.3.7 Summary

In summary, the data sets acquired and evaluated for the 903 Pad Project were satisfactory for supporting the Data Quality Objectives proposed in the SAP. The following project objectives were achieved:

- 1) Defining actinide activities that exceed 10 pCi/g <sup>241</sup>Am in surficial soils;
- 2) Defining actinide activities in surface and subsurface soil that exceed Tier I and II RSALs; and
- Defining VOC concentrations in subsurface soil that exceed current Tier I SSALs.

Although not required by the SAP, an additional evaluation was performed to define VOC concentrations in subsurface soils that exceed proposed Tier I and Tier II SSALs (Kaiser-Hill, 1999b). However, proposed Tier II SSALs are below the required detection limit for VOCs identified in the SAP (Appendix D). Although subsurface soils have been characterized with respect to the proposed Tier I SSALs, not all soils have been characterized with respect to proposed Tier II SSALs. Therefore, areas exceeding proposed Tier II SSALs may be underestimated.

903 Lip Area, and Americium Zone	Date:	September 28, 1999
	Page:	65 of 109

# 4.0 NATURE AND EXTENT OF CONTAMINATION

The nature and extent of soil contamination related to releases from the 903 Pad has been evaluated by analysis of radionuclide and chemical data obtained as described in Section 2. The primary objective of the investigation is to determine the areal extent and depth of radiological and organic contamination above Tier I RSALs and Tier I SSALs, respectively. Another objective of the investigation was to characterize <sup>241</sup>Am in surface soils to 10 pCi/g using gamma spectroscopy field instrumentation. This characterization would allow for identification of surface soils exceeding Tier II RSALs. Remedial alternatives will be evaluated in the IM/IRA decision document based on these criteria.

Detailed descriptions of contamination in surface and subsurface soil are presented in this section. Results of the HPGe survey of the Americium Zone are presented in Section 4.1. Sections 4.2 and 4.3 respectively summarize radionuclide and VOC soil data collected for the 903 Pad and Lip Area. Descriptive summary statistics of the data are presented in Appendix D. Electronic copies of analytical results and Tier I and Tier II RSAL calculations are provided in Appendix E.

#### 4.1 SOIL RADIOLOGICAL CONTAMINATION IN THE AMERICIUM ZONE

Results presented in this section are based on the double sampling technique in which HPGe measurements were correlated to alpha spectroscopy laboratory results. The linear regression between the HPGe results and laboratory results showed a high degree of correlation (R > 0.97), and was therefore used to standardize each HPGe measurement to laboratory derived alpha spectroscopy results (see Section 2.2.2). This provided an accurate model for estimating radiological contamination in surface soil relative to Tier I and Tier II RSALs at each survey location.

#### 4.1.1 Comparison of HPGe Measurements to Tier I and Tier II RSALs

Based on 1,110 HPGe measurements in the Americium Zone (Figure 2-1), radiological contamination appears to extend approximately 1,050 feet east of the Lip Area. Surface soil contamination is defined by Tier I and Tier II RSAL exceedances, which are summarized in Table 4-1. Using the best-fit regression model, nearly 37 % of the measurement locations exceed

Site Characterization Report for the	Document Number:	RF/RMRS-99-427.UN
903 Drum Storage Area,	Revision:	0
903 Lip Area, and Americium Zone	Date:	September 28, 1999
	Page:	66 of 109

the Tier II RSALs. Less than 1% of the measurement locations exceed the Tier I RSALs. HPGe results and RSAL calculations are presented in Appendix E.

Table 4-1 Frequency of RFCA Tier I and Tier II RSAL Exceedances-HPGe Survey Results

HPGe Survey	Number of Measurements	Number Of Exceedances RFCA Tier I RSALs	Number Of Exceedances RFCA Tier II RSALs
Surface Soil	1110	4	416

The range of measured <sup>241</sup>Am, <sup>239/240</sup>Pu, <sup>235</sup>U, and <sup>238</sup>U activities are presented graphically in Figure 4-1. Comparison of radionuclide results to Tier I and Tier II RSALs indicate that RSAL exceedances are due to elevated activities of <sup>239/240</sup>Pu and <sup>241</sup>Am. For <sup>239/240</sup>Pu, activities range from 6.32 pCi/g to 938.42 pCi/g with a mean value of 105.05 pCi/g. Approximately 7% of the <sup>239/240</sup>Pu measurements exceed the Tier II RSAL of 252 pCi/g. None of the <sup>239/240</sup>Pu measurements exceed the Tier I RSAL of 1429 pCi/g. <sup>241</sup>Am activities range from 4.91 pCi/g to 149.22 pCi/g with a mean value of 20.19 pCi/g. Approximately 10% of the <sup>241</sup>Am measurements exceed the Tier II RSAL of 38 pCi/g. Like <sup>239/240</sup>Pu, none of the <sup>241</sup>Am measurements exceed the Tier I RSAL of 215 pCi/g. HPGe measurements for <sup>235</sup>U and <sup>238</sup>U were all below Tier I and Tier II RSALs.

# 4.1.2 Spatial Distribution of Radiological Contamination in the Americium Zone

Figure 4-2 shows the distribution of Tier I and Tier II RSAL exceedances in surface soil within the Americium Zone. The highest level of contamination as indicated by Tier I RSAL exceedances is isolated at a cluster of three locations near the northwest corner of the Americium Zone and at one location in the south central portion of the Lip Area. Tier II exceedances encompass nearly 37% of the Americium Zone Investigation Area. The HPGe data also define the extent of soil contamination by bounding the area with survey results that are below Tier II RSALs (Figure 4-2). The accuracy of the HPGe survey data is corroborated by historical data as discussed in Section 2.2.2.1. The HPGe data also indicate, as expected, noncontaminated areas where clean fill was used for the road south of the cement and wetland areas, and for the road that borders the western and northern perimeter of the Americium Zone.

The Tier I and Tier II RSAL exceedances are associated with elevated activities of <sup>239/240</sup>Pu and <sup>241</sup>Am. The distribution of <sup>241</sup>Am activities is shown in Figure 4-3. The highest activities of <sup>241</sup>Am

Site Characterization Report for the	Document Number:	RF/RMRS-99-427.UN
903 Drum Storage Area,	Revision:	0
903 Lip Area, and Americium Zone	Date:	September 28, 1999
	Page:	67 of 109

exceed 140 pCi/g near the northwest corner of the Americium Zone. As shown, the distribution of <sup>241</sup>Am Tier II RSAL exceedances trend in a northeast-southwest orientation, which extends from the southwest corner of the Lip Area to the north-central portion of the Americium Zone. The distribution of <sup>239/240</sup>Pu activities in surface soil (Figure 4-4) is similar to that of the <sup>241</sup>Am activities, with the highest activities exceeding 900 pCi/g near the northwest corner of the Americium Zone. The pattern of Tier I RSAL exceedances is also similar to that observed for <sup>241</sup>Am, with a northeast-southwest trend of contamination. This trend is a result of contaminant deposition from the source area. The similar spatial configurations of <sup>241</sup>Am and <sup>239/240</sup>Pu are to be expected because <sup>241</sup>Am is a daughter product of weapons grade plutonium decay.

#### 4.1.3 FIDLER Surveys

A FIDLER survey was conducted at HPGe measurement location 301 (Figure 2-1) where an isolated HPGe measurement (direct field measurement) exceeded the 10 pCi/g <sup>241</sup>Am decision level. The FIDLER survey was used to determine if the result was caused by the presence of a smaller area containing a hot spot. It should be noted that all <sup>241</sup>Am activities discussed in this section are presented as direct field measurements. The activity of <sup>241</sup>Am from the *in situ* HPGe measurement location 301 was 10.977 pCi/g and the surrounding HPGe measurements were less than 10 pCi/g. FIDLER survey results ranged from 1,224 to 2,841 cpm with a mean of 2,056 cpm. Background measurements of 910 and 1,107 cpm for the two FIDLERs used for the survey were taken at the step-off pad on the north side of the Americium Zone, adjacent to the East Access Road. Because of the low level of <sup>241</sup>Am detected in the soil and two FIDLER instruments used for the survey, the results are qualitative at best. However, contamination appears to be homogeneous as would be expected at this distant location from the source where contamination is a result of wind dispersal of plutonium contaminated soil from the 903 Pad and Lip Area.

FIDLER surveys were also conducted at HPGe locations 460 and 462 (Figure 2-1) where surface soils exceeded the RFCA Tier I RSALs. The surveys were conducted to determine whether contamination was homogeneous and widespread as suggested by the conceptual model, or heterogeneous consisting of numerous individual hot spots. The activities of <sup>241</sup>Am from the *in situ* HPGe measurements were 115.74 and 109.04 pCi/g for HPGe measurement locations 460

Site Characterization Report for the	Document Number:	RF/RMRS-99-427.UN
903 Drum Storage Area,	Revision:	0
903 Lip Area, and Americium Zone	Date:	September 28, 1999
	Page:	68 of 109

and 462, respectively, and the surrounding HPGe measurements were less than 100 pCi/g. FIDLER survey results for HPGe measurement location 460 ranged from 2,928 to 17,039 cpm with a mean of 8,293 cpm. FIDLER survey results for FOV 462 ranged from 3,466 to 15,331 cpm with a mean of 8,729 cpm. Background measurements of 1,430 and 2,127 cpm for the two FIDLERs were taken at the step-off pad on the southwest corner of the Americium Zone, adjacent to the access road for the old firing range. Because two FIDLER instruments were used for the surveys, the results are qualitative. However, contamination appears to be heterogeneous and consists of numerous individual hot spots as might be expected from soil disturbance, localized erosional paths, or depositional areas near the source of contamination.

#### 4.2 SOIL RADIOLOGICAL CONTAMINATION IN THE 903 PAD AND LIP AREA

Surface and subsurface soil samples were analyzed for <sup>241</sup>Am, <sup>239/240</sup>Pu, <sup>233/234</sup>U, <sup>235</sup>U, and <sup>238</sup>U using alpha spectroscopy methods. Surface and subsurface soil samples were aggregated into four native soil horizons (Native 1 [0-6 in], Native 2 [6-12 in], Native 3 [12-18 in], Native 4 [18-24 in]), bedrock soil, and artificial fill under the 903 Pad. Artificial fill in the Lip Area was classified as Native 1 soil because native soil and artificial fill could not be differentiated in the field.

Based on the radiological results, contamination appears to be confined to the top 1.5 feet of native soil, and is most extensive in the Native 1 soil horizon. Table 4.2 summarizes the Tier I and Tier II RSAL exceedances. The frequency of Tier I and II exceedances decreases with increasing depth. No samples collected beneath the Native 3-soil horizon exceeded Tier I and Tier II RSALs<sup>2</sup>. Radiological data and RSAL SOR calculations for surface and subsurface soil are presented in Appendix E.

<sup>&</sup>lt;sup>2</sup> Radiological sample results from the subsurface VOC investigation indicate no contamination above Tier II RSALs. Activities of all measured radionuclides from the VOC investigation were below 3 pCi/g.

# 4.2.1 Radionuclide Activities in Native Soils

The range of activities for <sup>241</sup>Am, <sup>239/240</sup>Pu, <sup>233/234</sup>U, <sup>235</sup>U, and <sup>238</sup>U in Native 1, Native 2, and Native 3 soil types are shown graphically in Figure 4-5. As discussed in the following subsections, the amount of contamination decreases significantly with depth.

#### 4.2.1.1 Native 1 Surface Soil Contamination

The Native 1 soil has the most extensive contamination as indicated by activities of <sup>241</sup>Am, <sup>239/240</sup>Pu and <sup>231</sup>U that exceed Tier I and Tier II RSALs (Table 4-2 and Figure 4-5). <sup>238</sup>Uranium activities range from 0.49 pCi/g to 780 pCi/g with a geometric mean value of 1.99 pCi/g<sup>3</sup>. The high activity of 780 pCi/g is the only exceedance above Tier I and Tier II RSALs of 586 pCi/g and 103 pCi/g, respectively. Approximately 44 percent of the <sup>239/240</sup>Pu and <sup>241</sup>Am results exceed Tier II RSALs.

<sup>239/240</sup> Pu activities range from 0.82 pCi/g to 152,260 pCi/g with a geometric mean value of 146.69 pCi/g. For <sup>239/240</sup>Pu, 15% of the samples exceed the Tier I RSAL of 1,429 pCi/g and 44% of the samples exceed the Tier II RSAL of 252 pCi/g. <sup>241</sup>Am activities in Native 1 soil appear

<sup>&</sup>lt;sup>3</sup> The data appear to have a lognormal distribution, and therefore, a geometric mean is a better measure of the central tendency of the distribution.

Site Characterization Report for the	Document Number:	RF/RMRS-99-427.UN
903 Drum Storage Area,	Revision:	. 0
903 Lip Area, and Americium Zone	Date:	September 28, 1999
	Page:	70 of 109

more extensive than that of <sup>239</sup>Pu with activities ranging from 0.15 pCi/g to 31,670 pCi/g. For <sup>241</sup>Am activities, 19.1% of the samples exceed the Tier I (215 pCi/g) RSAL and 47.1% exceed the Tier II (38 pCi/g) RSAL.

#### 4.2.1.2 Native 2 Subsurface Soil Contamination

The Native 2 soil horizon is substantially less contaminated than the Native 1 soil horizon but still contains activities above Tier I and Tier II RSALs for <sup>241</sup>Am and <sup>239/240</sup>Pu (Figure 4-5). <sup>239/240</sup>Pu activities range from 0.14 pCi/g to 1,820 pCi/g with a geometric mean of 8.65 pCi/g. For <sup>239/240</sup>Pu, 0.03% of the samples exceed the Tier I RSAL (1,429 pCi/g) and 11% of the samples exceed the Tier II RSAL (252 pCi/g). <sup>241</sup>Am activities range from non-detectable (0.03 pCi/g) to 406 pCi/g with a geometric mean value of 1.79 pCi/g. <sup>241</sup>Am contamination is similar to that of <sup>239/240</sup>Pu contamination as indicated by frequency of exceedances of 0.03% and 11% above Tier I (215 pCi/g) and Tier II (38 pCi/g) RSALs.

#### 4.2.1.3 Native 3 Subsurface Soil Contamination

The amount of contamination in the Native 3 soil is minimal relative to the Tier II RSALs (Figure 4-5). Only one sample for <sup>241</sup>Am exceeds the corresponding Tier II RSAL of 38 pCi/g. <sup>241</sup>Am in the Native 3 soil horizon ranges from non-detectable to 54.40 pCi/g with a median value of 0.23 pCi/g<sup>4</sup>. Activities of <sup>239/240</sup>Pu in the Native 3 soil horizon were below the respective Tier I and Tier II RSALs.

# 4.2.2 Spatial Distribution of Contamination

Examination of the spatial distribution of contamination is useful for evaluating potential sources and contaminant migration pathways. This section discusses the spatial distribution of Tier I and Tier II RSALs for Native 1, Native 2, and Native 3 soil horizons. Also presented are the spatial distributions of <sup>239/240</sup>Pu and <sup>241</sup>Am activities because of their exceedance of Tier I and Tier II RSALs.

<sup>&</sup>lt;sup>4</sup> Due to the negative activities in the data set, the median value was used as a measure of the central tendency of the distribution instead of the geometric mean.

Site Characterization Report for the	Document Number:	RF/RMRS-99-427.UN
903 Drum Storage Area,	Revision:	0
903 Lip Area, and Americium Zone	Date:	September 28, 1999
	Page:	71 of 109

# 4.2.2.1 Spatial Distribution of Radionuclides in the Native 1 Soil Horizon

As shown in Figure 4-6, Tier I and Tier II RSAL exceedances (>1 for the sum of ratios) in Native 1 soil are located throughout the 903 Pad and Lip Area. There is no distinct pattern to the Tier I and Tier II exceedances at the 903 Pad. Most of the southern boundary and portions of the northern boundary do not exceed Tier II RSALs. For the Lip Area, Tier I exceedances are most prevalent in the center area due east of the 903 Pad, with Tier II exceedances surrounding this area. Relatively "clean" areas as indicated by RSALs less than Tier II are located further to the east and south of the 903 Pad. Apparent spatial gaps in contamination may be explained by past remedial activities. For example, the soil in the Lip Area was graded back toward the 903 Pad during past remedial actions, and therefore the soil closest to the Pad is not as contaminated as the soil near the central portion of the Lip Area. Similar remedial activities in 1984 removed contaminated soil in the western portion of the Lip Area.

The RSAL exceedances are associated with elevated levels of <sup>239/240</sup>Pu and <sup>241</sup>Am. Figure 4-7 shows the distribution of <sup>241</sup>Am in the Native 1 surface soil. The highest <sup>241</sup>Am activities exceed 30,000 pCi/g and are centered near boring 91598 (Figure 4-7). However, as shown in Figure 4-7, the majority of the Native 1 soils in the 903 Pad (approximately half of the Native 1 soil) and Lip Area exceed the Tier II RSAL for <sup>241</sup>Am of 38 pCi/g. The distribution of the <sup>239/240</sup>Pu activities is similar to that of the <sup>241</sup>Am activities, with the highest activities exceeding 150,000 pCi/g at boring 91598 (Figure 4-8). Like <sup>241</sup>Am, the <sup>239/240</sup>Pu activities are elevated with respect to the Tier II RSAL (252 pCi/g) in most of the Native 1 soil within the 903 Pad and approximately half of the Native 1 soil in the Lip Area.

#### 4.2.2.2 Spatial Distribution of Radionuclides in the Native 2 Soil Horizon

Figure 4-9 shows the distribution of the Tier I and Tier II RSAL exceedances (>1 for the sum of ratios) in the Native 2 soil horizon. The RSAL exceedances are not as ubiquitous as in the Native 1 soil horizon. RSAL exceedances are isolated to an area around boreholes 91398, 91598, 91898, and 91998 at the 903 Pad and around several boreholes throughout the Lip Area (boreholes 94898, 94998, 95198, 95398, 95498, 95598, and 97598). Like the Native 1 soil horizon, RSAL exceedances in the Native 2 soil horizon are associated with elevated levels of <sup>241</sup> Am and <sup>239</sup>Pu.

Site Characterization Report for the	Document Number:	RF/RMRS-99-427.UN
903 Drum Storage Area,	Revision:	0
903 Lip Area, and Americium Zone	Date:	September 28, 1999
	Page:	72 of 109

<sup>&</sup>lt;sup>241</sup>Am activities exceed 400 pCi/g in the 903 Lip Area with the highest activity observed at 95198 (Figure 4-10). The distribution of Pu-239 in the Native 2 soil horizon is very similar to that of <sup>241</sup>Am (Figure 4-11). <sup>239</sup>Pu exceeds 18,000 pCi/g (above the Tier I RSAL) at boring 95198. <sup>239/240</sup>Pu activities exceeding the Tier II RSAL (252 pCi/g) are distributed like the <sup>241</sup>Am activities (Figure 4-11). The <sup>239/240</sup>Pu and <sup>241</sup>Am activities in the Native 2 soil horizon are generally one to two orders of magnitude less than those observed in the Native 1 soil horizon.

Historical grading activity at the 903 Pad likely explains the somewhat different <sup>239/240</sup>Pu and <sup>241</sup>Am distributions between Native 1 and Native 2 soils. For example, grading activities at boring 91998 may have redistributed contamination in Native 1 soil leaving higher contaminated soils in the Native 2 soil horizon. In the Lip Area, the amount of artificial fill in the Native 1 soil horizon would explain higher activities in Native 2 soil relative to the Native 1 soil.

# 4.2.2.3 Spatial Distribution of Radionuclides in the Native 3 Soil Horizon

Figure 4-12 shows the distribution of the Tier II RSAL exceedances (>1 for the sum of ratios) in the Native 3 soil horizon<sup>5</sup>. The amount of radionuclide contamination in the Native 3 soil horizon is significantly less than that in the Native 1 and Native 2 soil horizons. Tier II RSAL exceedances are isolated along the northern boundary of the Lip Area at borings 94898 and 95198. One other isolated Tier II RSAL exceedance is observed east of the 903 Pad at boring 95498. Like the Native 1 and Native 2 soil horizons, the RSAL exceedances within the Native 3 soil horizon are associated with elevated levels of <sup>241</sup>Am and <sup>239/240</sup>Pu.

As shown in Figure 4-13, elevated levels of <sup>241</sup>Am with respect to the Tier II RSAL (38 pCi/g) are observed along the northern boundary of the Lip Area at boring 94898. Another area east of the 903 Pad near boring 95498 shows relatively high activities of <sup>241</sup>Am (up to 26 pCi/g) but these activities are slightly less than the Tier II RSALs<sup>6</sup>. The spatial distribution of <sup>239</sup>Pu in the Native 3 soil horizon is similar to that of <sup>241</sup>Am, (Figure 4-14). Although none of the <sup>239/240</sup>Pu samples exceed Tier I or Tier II RSALs, the relatively high activities near borings 94898 and 95498 contribute to the Tier II RSAL exceedances at these locations.

<sup>&</sup>lt;sup>5</sup> Tier I RSAL exceedances were not observed in the Native 3 Soil horizon.
<sup>6</sup> Tier I RSAL exceedances for <sup>241</sup>Am were not observed in the Native 3 Soil horizon.

Site Characterization Report for the	Document Number:	RF/RMRS-99-427.UN
903 Drum Storage Area,	Revision:	0
903 Lip Area, and Americium Zone	Date:	September 28, 1999
	Page:	73 of 109

Overall, the area of <sup>241</sup>Am and <sup>239/240</sup>Pu contamination decreases significantly with depth. Despite nearly identical spatial trends, the <sup>241</sup>Am and <sup>239</sup>Pu activities within the Native 3 soil horizon are an order of magnitude less than those within the Native 2 soil horizon.

# 4.2.3 Radionuclide Activities in 903 Pad Asphalt and 903 Pad Artificial Fill

Asphalt samples from the 903 Pad were collected to obtain preliminary estimates of the sample variance and mean for waste characterization purposes<sup>7</sup>. Random sampling techniques were used as an appropriate method to estimate the population mean and to determine the total amount of contamination. Nine asphalt samples were collected from sample locations randomly selected from the twenty-five 903 Pad subsurface soil sampling locations as shown in Figure 4-15. Asphalt thickness ranged from 0.4 to 0.7 feet with an average thickness of 0.5 feet. Twelve artificial fill samples were collected from locations randomly selected from the twenty-five 903 Pad subsurface soil sampling locations as shown in Figure 4-16. Artificial fill thickness ranged from 0.3 to 0.9 feet with an average thickness of 0.5 feet beneath the 903 Pad. Artificial fill results were compared to RFCA Tier I and Tier II RSALs. Samples were analyzed for <sup>241</sup>Am, <sup>239/240</sup>Pu <sup>233/234</sup>U, <sup>235</sup>U, and <sup>238</sup>U, using alpha spectroscopy methods. The descriptive summary statistics are provided in Appendix D.

# 4.2.3.1 Radionuclide Distribution in Asphalt

The radionuclide activities in asphalt were low relative to the activities observed in the Native 1 soil horizon. As shown in Figures 4-15 and 4-17, the activities for <sup>241</sup>Am, <sup>239/240</sup>Pu, <sup>233/234</sup>U, <sup>235</sup>U, and <sup>238</sup>U are all below 1.5 pCi/g. The mean, standard deviation, and other descriptive statistics are summarized in Table 4-3.

Figure 4-15 shows the distribution of radionuclides in asphalt. With the exception of <sup>238</sup>U, the highest radionuclide activities in asphalt are present at boring 91898 (<sup>233/234</sup>U [1.13 pCi/g], <sup>235</sup>U [0.133 pCi/g], <sup>241</sup>Am [0.341 pCi/g], and <sup>239/240</sup>Pu [1.22 pCi/g]). The highest <sup>238</sup>U (0.919 pCi/g) activity in asphalt was reported at boring 90198.

<sup>&</sup>lt;sup>7</sup> Asphalt samples were not comparable to RSALs, which are based the physical and chemical properties of soil. Instead, waste disposal WAC requirements for asphalt will be based on the mean and variance.

## 4.2.3.2 Radionuclide Distribution in 903 Pad Artificial Fill

The ranges of activities for the measured isotopes in artificial fill are presented in Figure 4-17. Overall, the radionuclide activities in artificial fill are low relative to the activities observed in the Native 1, Native 2, and Native 3 soil horizons. However, one Tier II RSAL exceedance is observed within the 903 Pad Area at boring 91898 (Figure 4-16). The Tier II RSAL exceedance is associated with elevated levels of <sup>241</sup>Am (126 pCi/g) and <sup>239/240</sup>Pu (558 pCi/g), which both exceed the respective Tier II RSALs of 38 pCi/g and 252 pCi/g. <sup>241</sup>Am activities in artificial fill range from 0.02 pCi/g to 126 pCi/g with a geometric mean value of 1.18 pCi/g. Elevated activities within the artificial fill appear to be isolated around this single boring considering that the highest <sup>233/234</sup>U (2.02 pCi/g), <sup>235</sup>U (0.49 pCi/g), <sup>233/234</sup>U (2.77 pCi/g), and <sup>239/240</sup>Pu (558 pCi/g) activities were also observed at boring 91898 (Figure 4-17). Descriptive summary statistics for the 903 Pad artificial fill are presented in Table 4-4.

#### 4.3 SUBSURFACE SOIL VOC INVESTIGATION

Seventeen boreholes were completed to investigate VOC contamination at the 903 Pad and Lip Area, which included the original 13 boreholes and four "step-out" boreholes (Figure 4-18). Subsurface soil VOC contaminants of concern as identified in the SAP (RMRS, 1998a) include carbon tetrachloride (CCl<sub>4</sub>), PCE, TCE, and 1,2-cis-dichloroethylene (1,2-DCE). Despite the absence of DNAPLs during drilling, VOCs were detected at several boring locations. As shown in Figure 4-18, detections of CCl<sub>4</sub> ranged from 2.3 ug/kg in borehole 96698 (22.4 to 22.8 ft) up to 5.3 ug/kg in borehole 96798 (20.4 to 20.8 ft). Detections of PCE ranged from 1.1 ug/kg in borehole 97698 (8.2 to 8.6 ft) up to 6,100 ug/kg in borehole 90998 (3.8 to 4.0 ft). Detections of TCE ranged from 0.89 ug/kg in borehole 96698 (20.4 to 20.8 ft) up to 290 ug/kg in borehole 90998 (3.8 to 4.0 ft). Detections of 1,2-DCE ranged from 1.1 ug/kg in boreholes 96798 (12.5 to

Site Characterization Report for the	Document Number:	RF/RMRS-99-427.UN

	Page:	76 of 109

12.9 ft) and 97698 (8.2 to 8.6 ft) up to 4,400 ug/kg in borehole 90998 (3.8 to 4.0 ft). In general, the majority of the VOC detections were observed in the northeastern quadrant of the 903 Pad at borings 90998, 95998, 96498, 96698, 96798, and 97698. VOC detections were also observed in the 903 Lip Area at boring 97298 and within the central portion of the 903 Pad at boring 96898. The ranges of VOC concentrations are presented in Figure 4-19.

No VOC detections were equal to or greater than the current Tier I SSALs (Table 4-5). However, proposed SSALs are 1 to 4 orders of magnitude less than the current Tier I SSALs (Table 1-2). Given the proposed SSALs, only one value (6,100 ug/kg observed at borehole 90998) exceeds the proposed Tier I SSAL for PCE (3,150 ug/kg). The VOCs that exceed the proposed Tier II SSALs include PCE, TCE, and 1,2-DCE (Table 4-5). As shown in Figure 4-18, the proposed Tier II exceedances are observed at boreholes 97698 (PCE), 96498 (PCE), 90998 (PCE,TCE, and 1,2-DCE), 95998 (PCE), and 96798 (PCE). The proposed Tier II SSAL exceedances occur within a relatively small area around monitoring well 08891. PCE is the most ubiquitous of the contaminants, occurring at five of the borings. The depth of contamination (relative to the proposed SSALs) varies from the 3.8 feet bgs at borehole 90998 to 24.6 feet bgs at borehole 95998. The proposed Tier II exceedances that occur below the water table are observed at borings 97698, 95998, and 96798.

Table 4-5. Frequency of VOC SSAL Exceedances in Subsurface Soil.

VOC	Number of Measurements	Number of Detections	Number Of Exceedances Current Tier I SSAL	Number Of Exceedances Proposed Tier I SSAL	Number Of Exceedances Proposed Tier II SSAL
Carbon Tetrachloride	86	3	0	0	0
PCE	86	19	0	1	7
TCE	86	7	0	0	1
1,2-DCE	32	1	0	0	1

Some of the deeper borehole samples may reflect solute (dissolved) concentrations in groundwater rather than concentrations in soil. Groundwater beneath the 903 Pad is relatively shallow with depth to water averaging approximately 19 feet below ground surface (bgs). During high flow regimes depth to water may decrease to 12 feet bgs. Therefore, it is likely that

Site Characterization Report for the	Document Number:	RF/RMRS-99-427.UN

903 Lip Area, and Americium Zone	Date:	September 28, 1999
	Page:	77 of 109

detections of CCL<sub>4</sub>, PCE and TCE observed at depths greater than 20 feet at boreholes 96698 and 96798 may represent partitioning of VOCs between the aqueous and solid phases.

The delineation of VOC contamination was optimized during the field investigation by the "stepout" boring approach (RMRS, 1998a). This decision making process was triggered by detections of VOCs above 10 percent of the respective current Tier I SSALs at any boring location. Such levels required an additional "step-out" boring approximately 20 feet in the upgradient direction from the boring where VOCs were detected at 10 percent of the current Tier I SSALs. Detections above 10 percent of the current Tier I SSALs were observed at borings 90998 and 95998. Borehole 90998 was completed as a shallow subsurface radiological borehole to a depth of 4.0 ft and based on field instrument readings a soil sample for VOC analysis was collected at a depth of 3.8 to 4.0 ft. As summarized above, the highest concentrations of PCE (6,100 ug/kg), TCE (290 ug/kg), and 1,2-DCE (4,400 ug/kg) were observed in borehole 90998. Concentrations of 1,2-DCE and PCE were above 10 percent of the current Tier I SSALs.

Borehole 96498 was completed to bedrock within one foot of borehole 90998 per the SAP (RMRS, 1998a) requiring completion of a shallow radiological borehole as a VOC borehole if VOCs were detected above 10 percent of the current Tier I SSALs. Similarly, borehole 95998 was completed to bedrock 20 ft in an upgradient direction west of boreholes 90998 and 96498. Detections of PCE (3,060 ug/kg), TCE (9.9 ug/kg), and 1,2-DCE (5.4 ug/kg) were observed in borehole 95998 at a depth of 5.0 to 5.6 ft. The concentrations of PCE that were observed in borehole 95998 were above 10 percent of the current Tier I SSAL. Therefore, borehole 97698 was completed in an upgradient direction 20 feet west of borehole 95998 in compliance with the SAP. Although PCE, TCE, and 1,2-DCE were detected in borehole 97698 none of the concentrations met or exceeded 10 percent of the current Tier I SSALs for the respective analytes.

# 5.0 CONTAMINTED MEDIA VOLUME ESTIMATES

Volume estimates of radiological and VOC contaminated surface and subsurface soil are based on the areal and vertical extent of contamination above Tier I and Tier II RSALs and proposed SSALs. An ArcInfo, version 7.2.2, Thiessen polygon command (ESRI, 1999) was used to determine areas exceeding action levels for subsequent in-place volume calculations. Remedial alternatives will be evaluated in the IM/IRA Decision Document based on these volume estimates. In-place volume estimates for the 903 Pad asphalt and artificial fill are also presented.

### 5.1 903 PAD ASPHALT AND ARTIFICIAL FILL VOLUME ESTIMATES

Characterization data for the asphalt comprising the 903 Pad were collected for waste characterization profiling, however, data were not compared to Tier I or Tier II RSALs. The estimated in-place volume of asphalt is 2,743 yds<sup>3</sup>. The estimated in-place volume of artificial fill is 2,743 yds<sup>3</sup>. The amount of radiologically contaminated artificial fill, relative to Tier II RSALs, beneath the 903 Pad is estimated at 104 yds<sup>3</sup>. The 104 yds<sup>3</sup> estimate is based on a 75 ft by 75 ft area surrounding boring 91898 and a 6 inch thickness of artificial fill. Table 5-1 summarizes the estimated areal extent, depth, and in-place volumes of asphalt and artificial fill for the 903 Pad.

Table 5-1 Summary of 903 Pad Asphalt and Artificial Fill Volumes

903 Pad	Depth (ft)	Area (ft²)	Volume <sup>1</sup> (ft <sup>3</sup> )	Volume <sup>1</sup> (yd <sup>3</sup> )	Volume <sup>1</sup> (m <sup>3</sup> )
Asphalt	0.5	148,104	74,052	2,743	2,097
Artificial Fill less than Tier II RSALs	0.5	142,479	71,239	2,639	2,017

# 5.2 TIER I RSAL EXCEEDANCE SOIL VOLUME ESTMATES

A composite map of the areal extent of Tier I RSAL exceedances in soil is presented in Figure 5-1. As shown, soil with radionuclides exceeding the Tier I RSALs is located at the 903 Pad, east of the 903 Pad in the Lip Area, and sporadically in the southern portion of the Lip Area and western portion of the Americium Zone. Table 5-2 summarizes the estimated areal extent, depth, and in-place volumes of soils exceeding Tier I RSALs by IHSS. The areal extent of Native 1 radiologically contaminated surface soil (relative to Tier I RSALs) is 120,360 ft<sup>2</sup>. Depth of contamination varies from 0 to 6 inches to 0 to 12 inches throughout the investigation area. Based on the areal and vertical extent of Tier I RSAL exceedances, the total volume of in-place radialogically contaminated soil is 2,924 cubic yards (yds<sup>3</sup>). The in-place volumes of contaminated soil by IHSS are as follows: 1,268 yds<sup>3</sup> for the 903 Pad; 1,598 yds<sup>3</sup> for the Lip Area; and 58 yds<sup>3</sup> for the Americium Zone.

Table 5-2 Summary of Radiologically Contaminated Soil Volumes-Tier I RSAL Exceedances

903 Pad	Depth (ft)	Area (ft²)	Volume <sup>1</sup> (ft <sup>3</sup> )	Volume <sup>1</sup> (yd <sup>3</sup> )	Volume <sup>1</sup> (m <sup>3</sup> )

#### 5.3 TIER II RSAL EXCEEDANCE SOIL VOLUME ESTIMATES

A composite map of the areal extent of Tier II RSAL exceedances in soil is presented in Figure 5-2. As expected, contamination above the Tier II RSALs is much more extensive than that of the Tier I RSAL exceedances. In general, Tier II RSAL exceedances encompass most of the 903

Site Characterization Report for the	Document Number:	RF/RMRS-99-427.UN

	Page:	99 of 109

Pad, the Lip Area, and the Americium Zone. Tier II RSAL exceedances in two portions of the Lip Area extend down to the Native 3 soil horizon, a depth of 1.5 feet. Figure 5-2 shows the areal extent of the Tier II RSAL exceedances for the Native 1 (0 to 6-inch), Native 2 (6 to 12-inch), and Native 3 (12 to 18-inch) soil horizons. Table 5-3 summarizes the estimated areal extent, depth, and in-place volumes of soils exceeding Tier II RSALs by IHSS.

The areal extent of Native 1 radiologically contaminated surface soil (relative to Tier II RSALs) is 700,698 ft<sup>2</sup>. Depth of contamination varies from 0 to 6 inches to 0 to 18 inches within the investigation area. Based on the areal and vertical extent of Tier II RSAL exceedances, the total volume of in-place radiologically contaminated soil is 14,763 yds<sup>3</sup>. A depth of 6 inches was used to estimate volumes of soil in the Americium Zone. Radiologically contaminated soil volumes based on Tier II RSAL exceedances are summarized in Table 5-3. The in-place volumes of contaminated soil by IHSS are as follows: 2,471 yds<sup>3</sup> for the 903 Pad, 5,267 yds<sup>3</sup> for the Lip Area; and 7,025 yds<sup>3</sup> for the Americium Zone.

Table 5-3 Summary of Radiologically Contaminated Soil Volumes-Tier II RSAL Exceedances

#### 5.4 SSAL EXCEEDANCE SOIL VOLUME ESTIMATES

VOC contaminants of concern (CCl<sub>4</sub>, PCE, 1,2-DCE, and TCE) did not exceed the current Tier I SSALs. However, as discussed in Section 4.3, PCE exceeds the proposed Tier I SSAL in boring 90998 (Figure 4-18). Proposed Tier II SSAL exceedances for PCE were also observed in five borings east of well 08891. 1,2-DCE exceeds the proposed Tier II SSAL in boring 90998. The areal extent of contamination was bounded one-half the distance between adjacent borings where VOC results were below their respective SSALs, and by the edge of the 903 Pad to the east. Several proposed Tier II SSAL exceedances were observed below the water table (average depth to water is 19 feet bgs) at boreholes 95998, 96798, and 97698. VOC contamination below the water table will be addressed under the groundwater program.

# 5.4.1 Tier I SSAL Exceedance Soil Volume Estimates

A composite map showing the areal extent of contamination as defined by the proposed Tier I SSALs is presented in Figure 5-3. The depth of VOCs that exceed proposed Tier I SSALs is assumed to extend from the natural soil surface below the top of the asphalt to 4.0 feet bgs (a thickness of 3.0 feet). This is a conservative assumption given that VOC samples were not collected above the four-foot sample interval. Based on the areal extent of the Tier I SSAL exceedances (5,017 ft²) and a thickness of 3.0 feet, the total in-place volume of contaminated soil is 558 yds³ (Table 5-4).

Table 5-4 Summary of Radiologically Contaminated Soil Volumes – SSAL Exceedances

Area/Volume	Volume <sup>1</sup> of Soils Greater Than Current Tier I SSALs (yds <sup>3</sup> )	Volume <sup>1</sup> of Soils Greater than Proposed Tier I SSALs (yds <sup>3</sup> )	Volume <sup>1</sup> of Soils Greater than Tier II SSALs (yds <sup>3</sup> )
Area with Soils Greater than Tier I and II RSALs	0	93	138
Area with Soils Less than Tier II RSALs	0	465	3,428
Total	0	558	3,566

Volume represents materials in-place volume.

	Page:	101 of 109

#### 5.4.2 Tier II SSAL Exceedance Soil Volume Estimates

A composite map showing the areal extent of contamination as defined by the proposed Tier II SSALs is presented in Figure 5-3. The areal extent of proposed Tier II SSAL contamination is slightly more extensive than that of Tier I SSAL contamination. The depth of VOCs that exceed Tier II SSALs is assumed to extend from the natural soil surface below the asphalt to 13.9 feet bgs (a thickness of 12.9 feet). This includes natural soils from the 1 foot to 4 foot interval where samples were not collected. Based on the areal extent of the Tier II SSAL exceedances (7,464 ft²) and a thickness of 12.9 feet, the total in-place volume of contaminated soil is 3,566 yds³ (Table 5-4).

# 5.5 RSAL AND SSAL EXCEEDANCE SOIL VOLUME ESTIMATES

Two areas within the 903 Pad contain surface soil with elevated levels of both radionuclides (RSALs) and VOCs (SSALs). Soil exceeding proposed SSALs occur in the two areas shown in Figure 5-3. Soil exceeding Tier I and Tier II RSALs are provided in Figures 5-1 and 5-2, respectively. Comparing these figures with Figure 5-3 shows that there are areas where both RSALs and SSALs exceedances overlap. Proposed Tier I SSAL exceedances in natural soils occur to a depth 4.0 feet. Tier I (and consequently Tier II) RSAL exceedances in natural soils are present to a depth of 6 inches in this area. Therefore, an estimated total of 93 yds<sup>3</sup> ([5,017 ft<sup>2</sup> x 0.5 ft]/27 ft<sup>3</sup>/yd<sup>3</sup>) of soils exceed both Tier I (and II) RSALs and proposed Tier I SSALs.

Proposed Tier II SSAL exceedances in natural soils occur to a depth 13.9 feet. Tier I (and consequently Tier II) RSAL exceedances in natural soils are present to a depth of 6 inches. Therefore, an estimated total of 138 yds<sup>3</sup> ([7,464 ft<sup>2</sup> x 0.5 ft]/27 ft<sup>3</sup>/yd<sup>3</sup>) of soils exceed both Tier I and II RSALs and proposed Tier II SSALs.

# 5.6 SSAL EXCEEDANCE SOIL VOLUME ESTIMATES (NON-RADIOLOGICALLY CONTAMINTED)

This section provides volume estimates of VOC contaminated soil (relative to SSALs) below the Native 1 soil horizon where radiologically contaminated soil (relative to RSALs) is not present.

Site Characterization Report for the	Document Number:	RF/RMRS-99-427.UN
903 Drum Storage Area,	Revision:	0
903 Lip Area, and Americium Zone	Date:	September 28, 1999
	Page:	102 of 109

The total in-place soil volume estimates, therefore, excludes the radiologically contaminated Native 1 soil addressed in Sections 5.2 and 5.3.

Soil exceeding SSALs occur in two areas within the 903 Pad (Figure 5-3). Proposed Tier I SSAL exceedances in natural soils occur to a depth 4.0 feet below the top of asphalt. Therefore, excluding the upper 1.5 feet of radiologically contaminated soil, the artificial fill and the asphalt (2.5 foot depth interval), a total of 465 yds<sup>3</sup> ([5,017 ft<sup>2</sup> x 2.5 ft]/27 ft<sup>3</sup>/yd<sup>3</sup>) of soil is estimated to exceed Tier I SSALs.

Proposed Tier II SSAL exceedances in natural soils occur to a depth of 13.9 feet below the top of asphalt. Excluding the upper 1.5 feet of radiologically contaminated soil, the artificial fill and the asphalt (12.4 foot depth interval), a total of 3,428 yds<sup>3</sup> ([7,464 ft<sup>2</sup> x 12.4 ft]/27 ft<sup>3</sup>/yd<sup>3</sup>) of soil is estimated to exceed Tier II SSALs.

#### 5.7 SUMMARY OF MEDIA VOLUME ESTIMATES

This section summarizes volume estimates of soils exceeding Tier I and Tier II RSALs and SSALs, and includes 903 Pad asphalt and artificial fill volume estimates. Table 5-5 presents volumes of asphalt, artificial fill and soil exceeding Tier I RSALs and SSALs.

Table 5-5 Volumes of Asphalt, Artificial Fill and Soils Exceeding Tier I RSALs and SSALs

903 Pad *In-Situ* Models and Uncertainties

### 903 PAD IN SITU MODELS AND UNCERTAINTIES

### In Situ Models

The Canberra in situ systems used to perform measurements at the RFETS 903 Pad project site employ the Canberra In Situ Object Counting System (ISOCS) software. This software package allows the user to calculate efficiencies for in situ quantification of defined objects using standard templates. One such template has been used to define the in situ measurement of contaminants in soils at the 903 Pad locations. This template requires the entry of various parameters which should accurately represent the actual conditions at the project site.

The template selected for this application is the circular plane source. This template requires the user to define a horizontal source size, a vertical source size, material composition and material density. In addition, the software uses detector specific physical parameters and user definable environmental parameters such as humidity, pressure and temperature. Each of these parameters has been defined in the model to represent actual conditions at 903 Pad, using existing knowledge of the site and project defined parameters. These parameter values, and the basis for selection, are described below.

Use of inappropriate values could lead to errors in *in situ* measurements. The model used for routine measurements contains the values most representative of actual conditions, however it is possible that actual measurement locations may vary from these assumed default conditions. Since it is not possible to verify all parameter values at each measurement location, default values will be used except where it is known that conditions vary significantly. An evaluation of the potential errors associated with deviation from default parameters has been performed and forms the basis of the total propagated measurement uncertainty (TMU) used when reporting *in situ* measurement results. These are also described below.

### Soil Density

The available soil density data from 903 Pad locations shows densities ranging from 1.0 to 1.3 g/cc. *In Situ* soil densities are typically on the order of 1.6 g/cc, but it is believed that, due to the lower moisture content of RFETS soils, this value may be too high. The ISOCS model uses a value of 1.3 g/cc as a mean value for 903 Pad soils.

### Uniformity

The uniformity, or non-uniformity, of contamination, both vertically and horizontally, will impact measurement results. Based on the mode of contamination deposition and on prior survey results (including *in situ* surveys), it is believed that the contamination is relatively uniform within the field of view in the ISOCS systems. This is a reasonable assumption since the in situ measurements integrate the readings over nearly 80 sq m areas. Thus, any individual "hot spots" are averaged over the entire area, or volume, and their impacts are minimized. The ISOCS model is based on uniform distributions.

### **Environmental Conditions**

Environmental temperature, humidity and pressure may impact some measurements. The ISOCS models assume standard environmental conditions; i.e. 20 C, 50 % relative humidity and 760 mm barometric pressure. Normal barometric pressure at RFETS is less, but the impact is negligible, as shown below.

### **Detector Parameters**

An ISOCS efficiency for each detector has been generated, using the specific detector characteristics, which tend to remain constant for long periods of time. The parameter of concern is the detector surface dead layer, which, if it increases could effect detection of low energy photons. This can be monitored by routine check source counts using a source with a low energy photon, such as Am-241. There have been no changes to these parameters over the course of the 903 Pad Project.

The ISOCS template used for the 903 Pad ISOCS efficiency is attached.

```
Default soil; Dry Dirt (490, 27Si, 4Fe, 1.6Mg, 4Ca, 2.7K, 7Al) Am-241 = 12.2 pCi/g
Dirt 2 (550, 31Si, 3Fe, 7Al) Am-241 = 11.6 pCi/g
Dirt 4 (450, 25Si, 12Fe, 2.5Mg, 4.1Ca, 2Mn, 8.3Al, 0.7Ti) Am-241 = 15.4 pCi/g
```

The overall impact of a likely range of compositions is about +/- 25%

### Soil Density

Soil densities were varied from the minimum of 1.0 to a maximum of 1,6 g/cc.

### Results

Default density 1.3 g/cc	Am-241 = 12.2 pCi/g
Density 1.6 g/cc	Am-241 = 12.0  pCi/g
Density 1.0 g/cc	Am-241 = 13.8 pCi/g

The overall impact of density changes is about +/- 10 %-

### **Environmental Conditions**

The default temperature and relative humidity are close to the ranges at RFETS but the default pressure is 20 % higher than normal barometric pressure at this altitude. However, changing the parameters to the RFETS values had no impact (same Am-241 results).

### **Detector Parameters**

Detector characteristics have been shown to be unchanged since factory calibration by verifying response by counting a standard reference material and obtaining the correct result. There is no error assigned to this.

### Data Quality Objectives for Measurement Data

Data Quality Objectives (DQOs) are qualitative and quantitative statements that describe the *in situ* characterization technical and quality objectives, define the appropriate type of data and specify acceptable levels of decision errors used to establish the quality of data. These data are used to assist RMRS in developing remedial action or management actions for the affected areas. For 903 Pad *in situ* measurements, the DQO is:

• To classify surface soils as exceeding Tier I soil action levels. This objective is met by measuring soil concentrations of Am-241, U-235 and U-238. Concentrations of Pu and other U isotopes are derived from these measurements. In order to provide sufficient margin for detection of Tier I levels, detection limits for the three nuclides measurable by *in situ* methods have been set at; 1 pCi/g Am-241, 0.5 pCi/g U-235 and 5.0 pCi/g U-238.

Data Quality Objectives used to validate all data generated by *in situ* measurements include the following: precision, accuracy, sensitivity, completeness, comparability and total uncertainty. For the 903 Pad Project, these are defined as follows:

- <u>Precision</u> A quantitative measure of the reproducibility or degree of agreement among replicate or duplicate measurements of a parameter. For the 903 Pad Project, precision shall be demonstrated by performing duplicate counts of specified soil locations on a frequency not to exceed once per 20 measurement locations. The reproducibility shall be calculate using accepted methods for evaluation of duplicate counting.
- Accuracy The degree of agreement between measured concentration values and the true or known values. For *in situ* measurements, true values are difficult to establish and may be estimated from alternate assay methods. For this project. *In situ* results will be compared to laboratory analyses of discrete soil samples. Comparable measurements at the action levels are expected to agree within +/- 50%. Evaluation of accuracy will be performed by RMRS and Canberra technical representatives.
- <u>Sensitivity</u> Sensitivity limits are defined as that level of radioactivity which, if
  present, will yield a measured value less than the critical limit with 5% probability.
  The critical limit is defined as that value which measurements of background will
  exceed with a 5% probability. Sensitivity limits for three detectable radionuclides are
  specified above.
- Completeness A quantitative measure expressed as a percentage of valid or acceptable data obtained from a measurement system. A goal of 90% has been set for this project.
